#### Abstract

I) $M_{r}=362 \cdot 1$, monoclinic, $C 2 / c, a=$ 15.055 (1), $\quad b=9.3782$ (7), $\quad c=11.714$ (1) $\AA, \quad \beta=$ $129.058(7)^{\circ}, \quad V=1284.3(2) \AA^{3}, \quad Z=4, \quad D_{x}=$ $1.873 \mathrm{~g} \mathrm{~cm}^{-3}, \mathrm{Cu} K \alpha, \lambda=1.5418 \AA, \mu=18.55 \mathrm{~cm}^{-1}$, $F(000)=728, T=298 \mathrm{~K}, R=0.047$ for $981 \quad$ 's $3 \sigma$ above background. A space-group ambiguity between $C 2$ and $C 2 / c$ was decided in favor of the latter by diffractometer $\psi$-scan measurements. Statistical tests gave contrary results. (II) $M_{r}=332 \cdot 1$, monoclinic, $P 2_{1} / c, a=6.283$ (1), $b=9.819$ (1), $c=18.679$ (3) $\AA$, $\beta=96.00(2)^{\circ}, \quad V=1146.0(4) \AA^{3}, \quad Z=4, \quad D_{x}=$ $1.925 \mathrm{~g} \mathrm{~cm}^{-3}, \mathrm{Cu} K \alpha, \lambda=1.5418 \AA, \mu=19.39 \mathrm{~cm}^{-1}$, $F(000)=664, T=298 \mathrm{~K}, R=0.055$ for $1509 I$ 's $3 \sigma$ above background. The formate ester (I) lies on a center of symmetry. The overall conformation is similar to that of 1,4-difluoro-1,1,4,4-tetranitro-2,3-butanediol and 1,4-difluoro-1,1,4,4-tetranitro-2,3-dinitrooxybutane. The conformation in the carbonate ester (II) is different. The $\mathrm{O}-\mathrm{C}$ and $\mathrm{C}=\mathrm{O}$ distances in the $-\mathrm{O}_{2} \mathrm{CH}$ group, compared with other esters, are distorted by the nearby $\mathrm{CF}\left(\mathrm{NO}_{2}\right)_{2}$ group by an effect which could be described as 'electron withdrawal inhibition of resonance'.

Introduction. The fluorodinitromethyl group is of interest as a substituent in energetic materials such as explosives and propellants. We are determining the structures of a number of high-crystal-density poly-nitro-group-containing organic compounds as a preliminary step in an investigation of the relationships between structure and crystal density in energetic substances. The structures of the formate (I) and cyclic carbonate (II) esters of 1,4-difluoro-1,1,4,4-tetranitro-2,3-butanediol are reported, and compared with the structures of the diol (III) (Dickinson \& Holden, 1979) and nitrate ester (IV) (Ammon \& Bhattacharjee, 1982).

(II) $X \cdots X=-\mathrm{C}(=\mathrm{O})-$
(III) $X=-\mathrm{H}$
(IV) $X=-\mathrm{NO}_{2}$

0108-2701/84/030487-04\$01.50

Experimental. Compounds obtained from Drs H. Adolph and W. Koppes, Naval Surface Weapons Center, Silver Spring, Maryland; formate ester recrystallized from acetone-hexane mixture (solvents dried over molecular sieves) as needles with triangular cross sections; carbonate ester obtained as needles with pentagonal cross sections by slow evaporation of a carbon tetrachloride solution. Picker FACS-I diffractometer, graphite monochromator. Formate ester (I): $0.31 \times 0.12 \times 0.10 \mathrm{~mm}$ crystal in glass capillary, cell parameters by least squares from 13 reflections manually centered at $\pm 2 \theta$ (average $\left|2 \theta_{o}-2 \theta_{c}\right|=$ $\left.0.004^{\circ}\right), \theta-2 \theta$ scan, $2^{\circ} \mathrm{min}^{-1}$, 10s backgrounds, $2 \theta$ scan width $1.3^{\circ}+0.29^{\circ} \tan \theta, 4$ standards every 100 reflections, av. and max. deviations from mean standard intensities 0.7 and $2.7 \%, 1549$ reflections measured, $2 \theta_{\text {max }} 127^{\circ}$, 1056 unique reflections, $9813 \sigma$ above background, max. and min. $h, k, l 17,10,10$ and $0,0,-13 ;$ mULTAN80 (Main, Fiske, Hull, Lessinger, Germain, Declercq \& Woolfson, 1980); max. and av. $4 / \sigma 0.777$ and 0.056 in final LS cycle; max. and $\min . \Delta \rho$ excursions in final difference map 0.22 and $-0.25 \mathrm{e}^{-3}$. Carbonate ester (II): $0.57 \times 0.32 \times$ 0.25 mm crystal, cell parameters by least squares from 13 reflections manually centered at $\pm 2 \theta$ (average $\left.\left|2 \theta_{o}-2 \theta_{c}\right|=0.008^{\circ}\right), \theta-2 \theta$ scan, $2^{\circ} \min ^{-1}, 10 \mathrm{~s}$ backgrounds, $2 \theta$ scan width $1.74^{\circ}+0.285^{\circ} \tan \theta, 4$ standards every 100 reflections, crystal decomposed slowly on exposure to atmosphere, av. and max. deviations from mean standard intensities 4.4 and $17.4 \%$ before scaling, 1.9 and $6.3 \%$ after scaling, 2341 reflections measured, $2 \theta_{\text {max }} 127^{\circ}, 1692$ unique reflections, $15093 \sigma$ above background; max. and min. $h, k, l$ $17,11,21$ and $0,0,-21$; structure solved with directmethods program PHASE in XRAY76 system (Stewart, Machin, Dickinson, Ammon, Heck \& Flack, 1976); max. and av. $\Delta / \sigma 0.128$ and 0.025 in final LS cycle; max. and min. $\Delta \rho$ excursions in final difference $\operatorname{map} 0.37$ and $-0.41 \mathrm{e}^{\AA} \AA^{-3}$.

Both structures refined by full-matrix least squares, minimizing $\sum w\left(F_{o}-F_{c}\right)^{2}, \quad w=[1 / \sigma(F)]^{2}$, reflections with $I_{c}<3 \sigma(I)$ omitted; anisotropic temperature factors for $\mathrm{C}, \mathrm{O}, \mathrm{N}$ and F , individual isotropic terms for $\mathrm{H} ; \mathrm{C}$, $\mathrm{N}, \mathrm{O}$ and F scattering factors from Cromer \& Mann © 1984 International Union of Crystallography
(1968), H from Stewart, Davidson \& Simpson (1965); $R, w R$ and $S$ for (I) $0.047,0.067,8.44$ and for (II) $0.055,0.092,2.40$; all calculations on a Univac 1100/82 computer at the University's Computer Science Center; majority of crystallographic calculations done with XRAY76 system (Stewart et al., 1976).

Discussion. We have assumed in this structure report that the space group of the formate ester is $C 2 / c$, with the $\mathrm{C}(1)-\mathrm{C}\left(1^{\prime}\right)$ bond across a center of symmetry. The original assignment was $C 2$, on the basis of several violations of the $h 0 l, l$ odd, systematic absences required by $C 2 / c$. For example, the values of $I$ and $\sigma(I)$ for several of the largest $h 0 l$ violators were $201=$ $1412(59), 401=3847(77), \quad 10,0, \overline{1}=1353(53)$ and $60 \overline{7}=1607(49)$. Consequently, the structure was solved and refined in $C 2$, but later refined in $C 2 / c$ when the symmetry of the $C 2$ molecule became clear. A preference for the $C 2$ structure was indicated by the Hamilton (1965) $R$-factor ratio test: the observed ratio $R(C 2 / c$ model $) / R(C 2$ model $)=1.228$ compared with the theoretical $\mathscr{R}_{160,851,0 \cdot 001}$ value of 1.127 suggested that the hypothesis that the $C 2 / c$ structure was correct could be rejected at the $99.9 \%$ confidence level. A more detailed test was made with the Prince (1982) method, which essentially involves a structure factor by structure factor comparison of two models. The test attempts to correlate the differences in the predictions of the models $\left(I_{c 1}, I_{c c}\right)$ with the differences between the observed values ( $I_{\partial}$ ) and the arithmetic means of the predictions, by determining the slope $(\lambda)$ of the line for $Z_{i}=I_{o i}-\frac{1}{2}\left(I_{c 1 i}+I_{c 2 i}\right)$ vs $X_{i}=\left(I_{c 1 i}-I_{c 2 i}\right)$ (i.e. $Z=\lambda X$; a positive slope favoring model 1 and a negative value model 2 ), and comparing $\lambda$ with its estimated variance. The comparison was set up with the $C 2$ structure as model 1, and the regression line calculated with 784 pairs of intensities [ $I_{c 1}$ and $\left.I_{c 2}>3 \sigma\left(I_{o}\right)\right]$ yielded a slope of +0.00033 and estimated variance of 0.00015 for the $99.9 \%$ confidence interval. These calculations indicate that the $C 2$ structure is a significantly better model for the data, in good agreement with the Hamilton $R$-factor method.

A final experimental check of the $h 0 l$ systematicabsence violations was accomplished by a series of diffractometer $\psi$-scan measurements. The original crystal of (I) had been lost by the time it became clear that additional experimental information on the $h 0 l$ systematic absences was required. A new crystal was mounted, but the orientation was such that a full $180^{\circ}$ rotation was possible for only the 401 . The relative intensity $[I, \sigma(I)]$ of the reflection was $44(29)$ at $\psi=0^{\circ}$, and $\psi$ rotation revealed several maxima, the largest of which was $5615(81)$ at $\psi=1 \cdot 2^{\circ}$. Thus, it would appear that the 401 is indeed unobserved (absent), and we have assumed that the other $h 0 l$ violators would show a similar behavior on $\psi$ rotation. The space group is,
therefore, $C 2 / c$, in contradiction of the indications obtained from the Hamilton and Prince tests.

Atomic coordinates and temperature factors are listed in Table 1* while bond lengths and angles are given in Tables 2 and 3. ORTEP drawings (Johnson, 1971) of the two molecules are given in Fig. 1.
(I), (III) and (IV) have similar conformations and each straddles a center of symmetry midway between $\mathrm{C}(1)$ and $\mathrm{C}\left(1^{\prime}\right)$. The $-\mathrm{O}-\mathrm{C}-\mathrm{CF}\left(\mathrm{NO}_{2}\right)_{2}$ fragments in the three structures were compared with Nyburg's (1974) best-molecular-fit program, giving r.m.s. deviations of $0.089 \AA$ for (I) $v s$ (III), $0.123 \AA$ for (I) $v s$ (IV) and $0.182 \AA$ for (III) $v s$ (IV). Variations in the torsion angles associated with the fluorodinitromethyl groups account for the major differences in the structures, viz the torsion angles $\mathrm{C}(1)-\mathrm{C}(2)-\mathrm{N}(1)-\mathrm{O}(1)$ and $\mathrm{C}(2)-\mathrm{C}(1)-\mathrm{N}(2)-\mathrm{O}(4)$ are 36.3 (3) and $-54.0(4)^{\circ}, 40.41$ (2) and -45.55 (4) and 20.7 (5) and -59.9 (5) in (I), (III) and (IV),

respectively. No specific structural features could be singled out to account for the $\mathrm{C}-\mathrm{C}-\mathrm{N}-\mathrm{O}$ torsionangle variations in these compounds. Crystal packing undoubtedly is a factor.

The r.m.s. deviation between the two $\mathrm{C}-\mathrm{CF}\left(\mathrm{NO}_{2}\right)_{2}$ moieties in the carbonate ester (II) is $0.163 \AA$, and the best fit between these fragments in (I) and (II) gives a r.m.s. deviation of $0.241 \AA$. The $\mathrm{C}-\mathrm{C}-\mathrm{N}-\mathrm{O}$ torsion angles in the two halves of (II) are different as is evident from $\mathrm{C}(3)-\mathrm{C}(4)-\mathrm{N}(3)-\mathrm{O}(5), \mathrm{C}(3)-\mathrm{C}(4)-$

Fig. 1.(a) ORTEP (Johnson, 1971) drawing of (I) with the C,N,O and F atoms depicted as $50 \%$ probability boundary ellipses. H atoms are shown as $0.1 \AA$ radius circles. (b) ORTEP drawing of (II) with the $\mathrm{C}, \mathrm{N}, \mathrm{O}$ and F atoms depicted as $50 \%$ probability boundary ellipses. H atoms are shown as $0.1 \AA$ radius circles.
$\mathrm{N}(4)-\mathrm{O}(7) \quad\left[26.7(3)\right.$ and $\left.-48.9(3)^{\circ}\right]$ and $\mathrm{C}(1)-$ $\mathrm{C}(2)-\mathrm{N}(1)-\mathrm{O}(1), \mathrm{C}(1)-\mathrm{C}(2)-\mathrm{N}(2)-\mathrm{O}(3) \quad[-8.8$ (4) and $58.3(3)^{\circ}$ ], the former showing a better agreement with the formate ester than the latter.

The fluorodinitromethyl lengths and angles in (I) (IV) are similar, with the largest deviations occurring in $\mathrm{C}(2)-\mathrm{N}(1) \quad\{1.526$ (5), $\quad[1.508(4), \quad 1.549$ (4)], 1.535 (5), 1.561 (5) $\AA\}$. The $\mathrm{CH}-\mathrm{OX}$ distances of 1.430 (3) in (I), 1.436 (3) and 1.437 (3) in (II), and 1.422 (4) $\AA$ in (IV), compared to the 1.400 (4) $\AA$ in diol (III), reflect a bond-lengthening effect by substitution of oxygen in (I), (II) and (IV).

There are only a few crystal structures of formate esters in the literature. The Cambridge Crystallographic Data Center (1982) files contained three formate ester entries, but coordinate data were available for only one, viz 4 -oxo-3-azatricyclo[7.3.1.0 ${ }^{3,8}$ ]tridec-11-yl formate (AZFXTD; Schagen, Overbeek, van der Putten \& Schenk, 1978). The -O-C=O distances of 1.326 (5) and 1.188 (6) $\AA$ in AZFXTD are similar to those reported in acetate esters, such as the 1.341 (4)
and $1 \cdot 186(5) \AA$ in methyl 2,3,4-tri- $O$-acetyl $-\beta$-Dlyxopyranoside (James \& Stevens, 1981). These distances differ from the $1 \cdot 374$ (6) and $1 \cdot 166$ (5) $\AA$ values in formate ester (I) in a way which suggests that of the two principal ester canonical forms, $-\mathrm{O}-\mathrm{C}=\mathrm{O} \leftrightarrow$ $-\mathrm{O}^{+}=\mathrm{C}-\mathrm{O}^{-}$, the dipolar contribution is disfavored in (I) compared to other esters. One might expect that the energy of the dipolar form in (I) would be raised by the adjacent electron-withdrawing $\mathrm{CF}\left(\mathrm{NO}_{2}\right)_{2}$ group, resulting in a smaller contribution to the resonance hybrid. This effect should lengthen the $\mathrm{O}-\mathrm{C}$ bond and shorten the $\mathrm{C}=\mathrm{O}$ bond. A similar phenomenon is present in nitrate ester (IV), in terms of the long $-\mathrm{O}-\mathrm{N}$ bond in the $-\mathrm{O}-\mathrm{NO}_{2}$ group.

The $\mathrm{C}=\mathrm{O}$ and $\mathrm{C}-\mathrm{O}$ stretching frequencies in the infrared spectra of (I) and (II) (Koppes, 1983) are consistent with ester and carbonate functionalities that contain smaller dipolar resonance form contributions than usual. The $v_{\mathrm{C}=0}$ and $v_{\mathrm{c}-\mathrm{o}}$ values of 1773 and $1090 \mathrm{~cm}^{-1}$ in (I), compared to 1720 and $1180 \mathrm{~cm}^{-1}$ in ethyl formate (Sadtler Standard Spectra, 1973), correspond to a stronger $\mathrm{C}=\mathrm{O}$ and weaker $\mathrm{C}-\mathrm{O}$. Bellamy (1964) has suggested that the $v_{\mathrm{c}=\mathrm{o}}$ of $1776 \mathrm{~cm}^{-1}$ in vinyl acetate is due to a decreased contribution of the dipolar resonance form. In carbonate ester (II), the $v_{\mathrm{C}=0}$ and $v_{\mathrm{C}-\mathrm{o}}$ of 1874 and $1146 \mathrm{~cm}^{-1}$, compared to 1800 and $1160 \mathrm{~cm}^{-1}$ in ethylene carbonate (Sadtler Standard Spectra, 1966), show the same trend.

The deviations of the five ring atoms in (II) from their LS plane are $\mathrm{C}(5) 0.011$ (2), $\mathrm{O}(9)-0.070$ (9), $\mathrm{O}(10)$ 0.070 (1), C(1) 0.207 (2), C(3) -0.187 (3) $\AA$ (LS plane program of Ito, 1982). The carbonate $\left(-\mathrm{O}_{2} \mathrm{C}=\mathrm{O}\right)$ is planar, and the remaining two ring carbon atoms are displaced by equal, but opposite, amounts from the $\mathrm{CO}_{3}$ plane. Since the two $\mathrm{CF}\left(\mathrm{NO}_{2}\right)_{2}$ substituents are cis, the ring twist is necessary to provide a staggered conformation about $\mathrm{C}(1)-\mathrm{C}(3)$. Bond lengths and angles of the ring compare well with similar parameters in five other ethylene carbonates found in the literature, the largest deviations being in the $\mathrm{C}-\mathrm{O}$ distances.

The intermolecular contacts in (I) are dominated by $\mathrm{O} \cdots \mathrm{O}$ and $\mathrm{F} \cdots \mathrm{O}$ interactions, while in (II) there is a larger number of $\mathrm{O} \cdots \mathrm{O}$ interactions and about equal numbers of $\mathrm{F} \cdots \mathrm{O}$ and $\mathrm{N} \cdots \mathrm{O}$ contacts. The shortest
$\mathrm{O} \cdots \mathrm{O}, \mathrm{F} \cdots \mathrm{O}$ and $\mathrm{N} \cdots \mathrm{O}$ contacts are 3.008 (5) $\left[\mathrm{O}(3) \cdots \mathrm{O}(6)\left(-x, y,-\frac{1}{2}-z\right)\right], 3.007(3) \quad[\mathrm{F}(1) \cdots \mathrm{O}(6)$ $\left.\left(x, 1-y, \frac{1}{2}+z\right)\right], 2 \cdot 794(4) \AA[\mathrm{N}(2) \cdots \mathrm{O}(5)(-x, 1-y,-z)]$ in (1) and $2.991(4) \quad\left[\mathrm{O}(7) \cdots \mathrm{O}(4) \quad\left(x, \frac{1}{2}-y, \frac{1}{2}+z\right)\right]$, 2.947 (3) $\left[\mathrm{F}(2) \cdots \mathrm{O}(7)\left(1-x, \frac{1}{2}+y, \frac{1}{2} z\right)\right]$ and 2.999 (4) $\AA$ $\left[\mathrm{O}(4) \cdots \mathrm{N}(4)\left(x, \frac{1}{2} y,-\frac{1}{2}+z\right)\right]$ in (II), respectively.
