parameters $U_{\text {eq }}$ extrapolated to 322 K from the structure of the low-temperature phase on the basis of the harmonic model for thermal vibrations. The estimated values are $U_{\text {eq }}(\mathrm{P})=1.53, U_{\text {eq }}|\mathrm{O}(1)|=2.8, U_{\text {eq }}[\mathrm{O}(2) \mid$ $=3.3, U_{\text {eq }}|\mathrm{O}(3)|=2.9$ and $U_{\text {eq }}[\mathrm{O}(4)]=3.1 \times 10^{-2} \AA^{2}$. It turns out that the observed values of $U_{\mathrm{eq}}$ at 322 K listed in Table 2 are still greater than the calculated ones by several tens of per cent or more. This fact suggests that the $\mathrm{PO}_{4}$ tetrahedra in the intermediate phase are disordered while they are ordered in the lowtemperature phase, indicating an order-disorder-type phase transition at 317 K .

Suzuki et al. (1983) reported that the hightemperature phase has the space group $P 2_{1} / m$ with the basis lattice parameters $a_{0}, b_{o}, c_{0}$. Therefore, it follows that the sequence of successive phase transitions is as follows: $P 2_{1} / m \quad\left(a_{o}, b_{o}, c_{o}\right) \rightarrow P 2_{1} / c \quad\left(a_{0}, b_{0}, 2 c_{o}\right) \rightarrow P 2_{1}$ ( $2 a_{o}, b_{0}, 2 c_{o}$ ) with decreasing temperature. The hightemperature phase transition can be interpreted by b-directed average atomic displacements alternately along $\mathbf{c}$ to destroy the reflection symmetry and to double the parameter $c$. The low-temperature phase transition is interpreted by $\mathbf{b}$-directed average atomic
displacements to form the sublattice structure and to double the parameter $a$. In fact, considerable atomic displacements along $\mathbf{b}$ are found by comparing the structure of the intermediate phase to that of the reported low-temperature phase. The observed ferrielectric activity along $\mathbf{b}$ can be understood by sublattice formation.

# Structure of Ammonium Dihydrogenphosphite, $\mathbf{N H}_{\mathbf{4}} \mathbf{H}_{\mathbf{2}} \mathrm{PO}_{\mathbf{3}}$ 

By Zdeněk Melichar, Bohumil Kratochvíl* and Jana Podlahová<br>Department of Inorganic Chemistry, Charles University, Albertov 2030, 12840 Praha 2, Czechoslovakia<br>and Václav Petříček, Karel Malý and Ivana Císařová<br>Institute of Physics, Czechoslovak Academy of Sciences, Na Slovance 2, 18040 Praha 8, Czechoslovakia

(Received 24 October 1983; accepted 3 January 1984)

Abstract. $\quad M_{r}=99.026$, monoclinic, $\quad P 2_{1} / c, \quad a=$ 6.273 (1), $\quad b=8.232$ (2), $\quad c=8.902$ (2) A,$\quad \beta=$ 120.11 (2) ${ }^{\circ}, V=397.7$ (2) $\AA^{3}, Z=4, D_{m}=1.672$ (3), $D_{x}=1.654 \mathrm{Mg} \mathrm{m}^{-3}, \quad \lambda(\mathrm{Mo} K \alpha)=0.71069 \AA, \quad \mu=$ $0.54 \mathrm{~mm}^{-1}, F(000)=208, T=298 \mathrm{~K}$. Final $R=0.055$ for 1155 unique reflections. $\mathrm{HPO}_{3}$ tetrahedra are connected through $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds so that infinite chains of composition $\left(\mathrm{H}_{2} \mathrm{PO}_{3}\right)_{n}^{n-}$ are formed in the structure parallel to the $z$ axis. The chains are further interwoven together by means of $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds originating from the $\mathrm{NH}_{4}^{+}$ions, forming a three-dimensional network.

[^0]0108-2701/84/050720-03\$01.50

Introduction. The preparation of $\mathrm{NH}_{4} \mathrm{H}_{2} \mathrm{PO}_{3}$ has been described by Amat (1891), and Ebert \& Grospietsch (1968) found exact conditions for its formation from the solubility diagram of the $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{HPO}_{3}-\mathrm{H}_{3} \mathrm{PO}_{3}-$ $\mathrm{H}_{2} \mathrm{O}$ system at 298 K . Preliminary crystal data (cell dimensions, space group, density) were determined by Norbert, Brun, Maurin \& Barnoyer (1971). A crystalstructure study of $\mathrm{NH}_{4} \mathrm{H}_{2} \mathrm{PO}_{3}$ was undertaken as part of an investigation of hydrogenphosphites.

Experimental. Spherical crystal, $r=0.8 \mathrm{~mm}, \mu r=$ $0 \cdot 43$, absorption ignored, Hilger \& Watts diffractometer, lattice parameters refined from the setting of 29 centered high-angle reflections, 1233 reflections

measured by the learnt profile method (Clegg, 1981), $0<2 \theta<60^{\circ}, \quad h \in\langle-8,7\rangle, \quad k \in\langle 0,11\rangle, \quad l \in\langle 0,12\rangle$, no significant intensity variation in three standard reflections, 1155 unique reflections, 50 unobserved reflections $\left[I<1 \cdot 96 \sigma_{1}(I)\right]$, heavy-atom method, H -atom positions from $\Delta F$ synthesis, the quantity $\sum w\left(F_{o}-\right.$ $\left.\left|F_{c}\right|\right)^{2}$ minimized by full-matrix least squares, 71 parameters refined: scale factor, positions and anisotropic temperature factors of non- H atoms, positions and isotropic temperature factors of H atoms, isotropic extinction value $\left[g=1 \cdot 12(6) \times 10^{-5}\right], R=0.055, w R$ $=0.076, w=1 /\left[\sigma^{2}\left(F_{o}\right)+0.019461 F_{o}{ }^{2}\right]$ derived from $\sigma\left(F_{o}\right) /\left|F_{0}\right|=\frac{1}{2}\left[\sigma_{2}(I) / I\right]$ and $\sigma_{2}(I)=\left[\sigma_{1}^{2}(I)+\left(0.06 I^{2}\right]^{1 / 2}\right.$, $(\Delta / \sigma)_{\text {max }}=0.09$, max. height in final $\Delta F$ map $0.5 \mathrm{e} \AA^{-3}$, programs SHELX76 (Sheldrick, 1976)source of scattering factors for neutral atoms, TLS (Sklenár \& Petříček, 1981), ORTEP (Johnson, 1965), ICL 4-72 computer.

Discussion. The atomic parameters are given in Table 1 and the interatomic distances and angles in Table 2.* Every P atom is surrounded by three O atoms and one H atom in a tetrahedral configuration (Fig. 1). All values of the interatomic distances and angles are in accordance with the literature data, except for the $\mathrm{O}(1)-\mathrm{H}(\mathrm{O})$ distance, which is slightly shorter. During refinement the $\mathrm{H}(\mathrm{O} 1)$ atom always moved close to the $\mathrm{O}(1)$ atom regardless of the extinction-correction set.

The structure is related to those of $\mathrm{LiH}_{2} \mathrm{PO}_{3}$ [Philippot \& Lindqvist, 1970 (X-ray data); Johansson \& Lindqvist, 1976 (neutron data)] and $\mathrm{KH}_{2} \mathrm{PO}_{3}$ (K ratochvil, Podlahová \& Hašek, 1983). The phosphite tetrahedra are connected through the hydrogen bonds to form infinite chains of the $\left(\mathrm{H}_{2} \mathrm{PO}_{3}\right)_{n}^{n-}$ composition. The chains are held together by means of the electrostatic forces between the chains and the $\mathrm{Li}^{+}$or $\mathrm{K}^{+}$ions. In the $\mathrm{NH}_{4} \mathrm{H}_{2} \mathrm{PO}_{3}$ structure the chains are parallel to the $z$ axis and are formed through the $\mathrm{O}(1)-\mathrm{H}(\mathrm{Ol}) \cdots \mathrm{O}(2)$ interaction.

The $\mathrm{NH}_{4}^{+}$tetrahedron is slightly distorted, the $\mathrm{N}-\mathrm{H}$ distances varying in the range of usual values. The ammonium ion is firmly fixed in the structure by means of four $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds, which prevent free ammonium-ion rotation at 298 K . Only the $\mathrm{O}(2)$ and $O(3)$ atoms act as proton acceptors; the $O(1)$ atom does not take part in the $\mathrm{N} \cdots \mathrm{O}$ hydrogen bonding.

All hydrogen bonds ( $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ types) give rise to a three-dimensional network in the structure. A similar structural motif with fixed $\mathrm{NH}_{4}^{+}$ positions was found in $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{HPO}_{3} \cdot \mathrm{H}_{2} \mathrm{O}$ (Rafiq, Durand \& Cot, 1982) and $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{Sn}\left(\mathrm{HPO}_{3}\right)_{2}$ (Yamaguchi \& Lindqvist, 1982).

# Structure of a Second Form of 1,2;2,3-Di- $\mu$-hydrido- $\mu_{3}$-tetracarbonylferrio-cyclo-tris (tricarbonylruthenium) $(3 \mathrm{Ru}-\mathrm{Ru}), \mathrm{H}_{2} \mathrm{FeRu}_{3}(\mathrm{CO})_{13}$ 

By Leh-Yeh Hsu, Alak A. Bhattacharyya and Sheldon G. Shore*<br>Department of Chemistry, The Ohio State University, Columbus, Ohio 43210. USA

(Received 29 September 1983: accepted 15 November 1983)

#### Abstract

M_{r}=725.21\), monoclinic, $C 2 / c, \quad a=$ 31.418 (6) , $\quad b=9.724$ (3), $\quad c=13.816(1) \AA, \quad \beta=$ $110.83(1)^{\circ}, \quad V=3945.0 \AA^{3}, \quad Z=8, \quad D_{x}=$ $2.442 \mathrm{~g} \mathrm{~cm}^{-3}, F(000)=2736$, Mo $K \alpha, \lambda=0.71073 \AA$. $\mu=29.970 \mathrm{~cm}^{-1}$, room temperature, $R=0.043$ for 3546 reflections. Crystals were grown from a tetrahydrofuran (THF) solution at room temperature to which $\mathrm{Et}_{2} \mathrm{O}$ was added. The molecule contains a distorted tetrahedral $\mathrm{FeRu}_{3}$ cluster. The molecules are aligned parallel to the plane (111).

Introduction. From the attempted synthesis of $\mathrm{H}_{2} \mathrm{Fe}_{3} \mathrm{Ru}_{3}(\mathrm{CO})_{18}$ by protonating with HCl an equimolar mixture of $\mathrm{K}_{2}\left[\mathrm{Ru}_{3}(\mathrm{CO})_{11}\right]$ and $\mathrm{Fe}_{3}(\mathrm{CO})_{12}$ in THF a product was obtained which upon crystallization by adding $\mathrm{Et}_{2} \mathrm{O}$ proved to be a previously unreported crystalline form of the known compound $\mathrm{H}_{2} \mathrm{FeRu}_{3}(\mathrm{CO})_{13}$ (Gilmore \& Woodward, 1971). The previous description of this compound, form (I) (space group $P 2_{1} / a$, two independent molecules in the asymmetric unit), differs markedly in shape and color from form (II) (space group $C 2 / c$, one independent molecule in the asymmetric unit) reported here. The more accurate and more extensive data obtained in the present study enable us to determine with greater accuracy and precision the molecular parameters of $\mathrm{H}_{2} \mathrm{FeRu}_{3}(\mathrm{CO})_{13}$ and to elucidate molecular features which were tentatively suggested in the earlier report. Furthermore, it is of interest to examine and compare the packing of molecules in each crystalline form.

[^2]0108-2701/84/050722-04\$01.50

Experimental. Crystal $0.12 \times 0.30 \times 0.35 \mathrm{~mm}$. dark brown, plate-like. Enraf-Nonius CAD-4 diffractometer, graphite-monochromated Mo $K \alpha$ radiation. Cell dimensions: least-squares fitting from 24 reflections well distributed in reciprocal space, $2 \theta$ range $15-30^{\circ}$. Data collected by $2 \theta: \theta$ scan mode. $2 \theta$ range $4-55^{\circ}$. Intensities in $h k l$ and $h k \bar{l}$ octants measured. Total of 4885 reflections collected, 4512 unique: 3546 with $I>$ $3.0 \sigma(I)$ used in structure refinement. Six standard intensities: max. variation 0.03 . Intensities corrected for Lorentz and polarization effects and also for absorption by using the method of Gaussian quadrature with grid $18 \times 14 \times 4$ points: max. and min. transmission coefficients 0.7352 and 0.3424 . Analytical form of scattering factors for neutral atoms used. $f^{\prime}$ and $f^{\prime \prime}$ terms included for all atoms (Cromer \& Waber, 1974). All crystallographic computations carried out on a PDP 11/44 computer using the Enraf-Nonius Structure Determination Package. Intensity statistics indicated the space group likely to be the centrosymmetric $C 2 / c$. rather than $C c$. Structure solved by MULTAN11/82 (Frenz. 1982: Hull \& Irwin. 1978: Yao, I981). Full-matrix least-squares refinement (anisotropic thermal parameters) minimizing $\left\lfloor\mathfrak{u}\left(\left|F_{0}\right|-\left|F_{c}\right|\right)^{2}: \mathfrak{H}=\left|\sigma(I)^{2}+(p l)^{2}\right|^{12}\right.$. with $p=0.06$ chosen to make $\leq \backsim \Delta F^{2}$ uniformly distributed in $\left|F_{"}\right|$. A difference Fourier synthesis gave the coordinates of two bridging H atoms. These were included with isotropic $B=4.5 \AA^{2}$. No H parameters were refined. Final $R=0.043$ and $R_{w}=0.064$. Final difference Fourier map showed no significant features, with a max. peak height of $0.66 \mathrm{e}_{\AA^{-3}}$ in the vicinity of the Ru atom. $(\Delta / \sigma)_{\max }=-0.15$.
