Upon storage at room temperature for about a year the crystals of the hydrogen oxalate of formamide oxime undergo solid-state transformation into a new crystalline form. Several crystal modifications, including the above-mentioned, have been observed during the crystallization work, all with a short needle axis of about $3 \cdot 5 \AA$.

The author wishes to thank Mr Flemming Hansen for collecting the data for the structure determination. The diffractometer and an X-ray generator were
acquired by means of Grants 11-1837, 11-2360, and 11-3531 from the Danish Natural Science Research Council.

(Received 23 July 1984; accepted 1 January 1985)

Abstract. $M_{r}=278.3$, orthorhombic, $P c a 2_{1}, \quad a=$ 12.614 (5), $\quad b=11.278$ (4), $\quad c=9.374$ (8) $\AA, \quad V=$ $1333.6(2) \AA^{3}, \quad Z=4, \quad D_{m}=1.378(5), \quad D_{x}=$ $1.386(5) \mathrm{Mg} \mathrm{m}^{-3}, \quad \lambda(\mathrm{Mo} K \alpha)=0.71069 \AA, \quad \mu=$

[^0] 0108-2701/85/050752-04\$01.50
$0.238 \mathrm{~mm}^{-1}, \quad F(000)=584, \quad T=293 \mathrm{~K}$. Final $R=$ 0.037 for 2006 observed reflections. The angle of twist between the planes of the two rings is $78.6(2)^{\circ}$. The benzene ring is planar while the pyrimidine ring is slightly folded about the $\mathrm{C}(12)-\mathrm{N}(15)$ axis. The geometry around the sulphur atom is distorted from the
ideal tetrahedral symmetry. The molecule shows a gauche conformation about the $\mathrm{S}-\mathrm{N}$ bond with a torsion angle of $59.6(2)^{\circ}$. The crystal structure is stabilized by a network of hydrogen bonds and van der Waals forces. The molecules are stacked together along the diagonals of the $a b$ plane.

Introduction. The sulphonamides are well known antibacterial drugs in some common bacterial diseases. They exert their antibacterial action by inhibiting competitively with para-aminobenzoic acid (PABA) the enzyme dihydropteroate synthase (DHPS). The inhibition of this enzyme leads to bacteriostasis. As part of our programme on systematic studies on sulphonamides and the enzyme DHPS (Singh, Patel \& Haridas, 1984), we report here the crystal structure of sulfisomidine. A brief report on the structure solution was made earlier (Reinhardt, Tiwari \& Singh, 1980).

Experimental. Sulfisomidine samples synthesized by Nordmark Werke GmbH, Hamburg (Germany) and obtained on the open market in the form of tablets, crystallized from solution in acetone.Thin needle-like crystals: one $0.70 \times 0.30 \times 0.29 \mathrm{~mm}$ used for data collection. Unit-cell dimensions and space group from oscillation and Weissenberg photographs and diffractometry. Unit-cell dimensions refined using 24 highangle reflections ( $\theta$ range: 25 to $43^{\circ}$ ). Density by flotation in benzene/carbon tetrachloride. Intensity data collected on a computer-controlled Siemens four-circle diffractometer using Nb -filtered Mo K $\alpha$ radiation. Total number of reflections measured 3478 , total number of independent reflections 2434, observed reflections $(I \geq 2 \sigma) 2006$, for $\sin \theta / \lambda \leq 0.75 \AA^{-1}$ with $h= \pm 18$, $k= \pm 16, \quad l=13$. Corrections for Lorentz and polarization effects but not for absorption ( $\mu r=0.071$ ), $R_{\text {int }}$ (for merged data) $=0.027$. Intensity measurements of standard reflections 002 and 600 repeated after every 50 reflections, variations in intensity throughout experiment $\leq 2.8 \%$. Partial structure solved by MULTAN (Germain, Main \& Woolfson, 1971) and remaining atoms from $\Delta \rho$ maps. The $z$ coordinate of the sulphur atom was held fixed to specify the origin. Refinement by full-matrix least-squares procedure. Positions of hydrogen atoms by successive $\Delta \rho$ maps. Parameters refined using anisotropic temperature factors for non-hydrogen atoms and isotropic temperature factors for hydrogen atoms. Final $R$ for 2006 reflections $=0.037, w R$ $=0.036, S=3.60$. All observed reflections given unit
weights which gave a minimum variation of $R$ as a function of $2 \theta . \quad(\Delta / \sigma)_{\max }=0.058$, final excursions $=-0.14$ to $0.16 \mathrm{e} \AA^{-3} .\left|F_{o}\right|$ used in full-matrix leastsquares refinement using XRAY76 (Stewart, Machin, Dickinson, Ammon, Heck \& Flack, 1976). Atomic scattering factors of Cromer \& Mann (1968) for C, N, O and S and of Stewart, Davidson \& Simpson (1965) for H. Calculations on the Cyber computer at FU Berlin and HP-1000 system at AIIMS, New Delhi.

Discussion. The final positional and equivalent isotropic temperature factors of non-hydrogen atoms are given in Table 1.* The bond lengths and angles involving non-hydrogen atoms are listed in Table 2. The stereoscopic view with thermal ellipsoids is illustrated in Fig. 1. The crystal structure, hydrogen-bonding scheme and the numbering system are shown in Fig. 2. The average $\mathrm{C}-\mathrm{H}$ and $\mathrm{N}-\mathrm{H}$ distances are 0.89 (5) and 0.78 (6) $\AA$ respectively. The bond lengths and angles in the benzene ring are normal. The bond lengths in the pyrimidine ring range from 1.323 (4) to 1.414 (4) $\AA$ and valency angles from 118.0 (3) to 122.1 (3) ${ }^{\circ}$. These values are, in general, in good agreement with those found in a standard pyrimidine ring. The value of the endocyclic angle $\mathrm{N}(13)-\mathrm{C}(14)-\mathrm{N}(15)$ is 122.1 (3) ${ }^{\circ}$. The corresponding angle is 129.5 (9) ${ }^{\circ}$ in sulfadimidine (Tiwari, Haridas \& Singh, 1984), 129 (1) ${ }^{\circ}$ in sulfadimethoxine (Patel, Tiwari, Patel \& Singh, 1983), $128.0(10)^{\circ}$ in sulfadiazine (Joshi, Tiwari, Patel \& Singh, 1983), and $127 \cdot 1$ (7) ${ }^{\circ}$ in sulfamerazine (Ravindra Acharya, Kuchela \& Kartha, 1982). The large difference is, perhaps, due to the difference in the size of the substituent at the $\mathrm{C}(14)$ atom. In the title compound, the substituent at $\mathrm{C}(14)$ is a methyl group whereas in the others the substituents are more bulky.

The bonding around the sulphur atom is distorted from the ideal tetrahedral geometry. The maximum and minimum values of angles around the sulphur atom are 115.5 (3) and $103.9(3)^{\circ}$ respectively. The deviation from the tetrahedral configuration of $109.5^{\circ}$ probably results from steric hindrance of dissimilar groups and from the type of non-bonded interactions described by Bartell (1962). The bond distances around the sulphur atom are $\mathrm{S}(8)-\mathrm{C}(1)=1.755(3), \quad \mathrm{S}(8)-\mathrm{O}(9)=$ $1.430(2), \mathrm{S}(8)-\mathrm{O}(10)=1.451(2)$ and $\mathrm{S}(8)-\mathrm{N}(11)$ $=1.630$ (3) $\AA$. Abrahams (1955) has calculated the $\mathrm{S}-\mathrm{C}$ single-bond distance to be $1.82 \AA$ which is close to the sum of the Pauling (1960) covalent radii for sulphur and carbon atoms. On this evidence, the

Fig. 1. Molecular structure viewed along [001].
$\mathrm{S}(8)-\mathrm{C}(1)$ bond distance of 1.755 (3) $\AA$ appears to be considerably shorter. Schomaker \& Stevenson (1941) have estimated the $\mathrm{S}-\mathrm{N}$ single bond to be $1.74 \AA$, while in sulphamic acid (Sass, 1960) where the nitrogen atom has no orbital available for $\pi$-bonding, the $\mathrm{S}-\mathrm{N}$ link is 1.76 (2) $\AA$. Both of the above values are significantly greater than the $\mathrm{S}(8)-\mathrm{N}(11)$ distance of 1.630 (3) $\AA$ in sulfisomidine indicating a considerable double-bond character for this bond. Cruickshank (1961) has assigned the bond orders of about 0.66 for $\mathrm{S}-\mathrm{O}$ bonds in the region of $1.43 \AA$. The two $\mathrm{S}-\mathrm{O}$ bonds in the present structure $[1.430(3), 1.451$ (2) $\AA$ ] therefore possess considerable double-bond character. They also differ from each other by $0.021 \AA$ which is significant. This may be related to the hydrogen-bond characteristics because $O(10)$ is a proton acceptor in an intermolecular hydrogen bond $\mathrm{N}(7)-\mathrm{H}(71) \cdots \mathrm{O}(10)$ while $O(9)$ does not participate in such an interaction. Recent studies on the behaviour of bonding around the sulphur atom for a large number of structures containing the $N$-substituted-arylsulphonamide moiety have been reported by Kálmán, Czugler \& Argay (1981), the results of which generally conform to the above observations.

The benzene ring is planar whereas the pyrimidine ring is slightly folded along the line $\mathrm{C}(12)-\mathrm{N}(15)$. Atoms $\mathrm{C}(12), \mathrm{N}(13), \mathrm{C}(14)$ and $\mathrm{N}(15)$ are coplanar while the atoms $\mathrm{N}(15), \mathrm{C}(16), \mathrm{C}(17)$ and $\mathrm{C}(12)$ are almost coplanar. The dihedral angle between the best least-squares planes of the halves of the pyrimidine ring is $4.0(2)^{\circ}$. This distortion is similar to that observed in the pyrimidine ring of barbital (Patel \& Singh, 1984). The planes of the two rings are rotated with respect to each other at $78.8(2)^{\circ}$. The molecule maintains a gauche conformation about the $\mathrm{S}(8)-\mathrm{N}(11)$ bond with a torsion angle of $59.6(2)^{\circ}$. The dihedral angles between the planes $\mathrm{C}(1)-\mathrm{S}(8)-\mathrm{O}(9)$ and $\mathrm{C}(1)-\mathrm{S}(8)-$ $\mathrm{O}(10)$, and $\mathrm{N}(11)-\mathrm{S}(8)-\mathrm{O}(9)$ and $\mathrm{N}(11)-\mathrm{S}(8)-\mathrm{O}(10)$ are $69 \cdot 1$ (2) and $54 \cdot 1$ (2) ${ }^{\circ}$ respectively.

Fig. 2. The molecular packing in the crystal structure as viewed along the $c$ axis. The hydrogen bonds are shown by broken lines.

The molecular packing of sulfisomidine as seen down the $c$ axis is shown in Fig. 2. The dotted lines indicate the hydrogen bonds. The amino nitrogen atom N(7) is a proton donor in a hydrogen bond with $\mathrm{O}(10)$ of the symmetry-related molecule $[\mathrm{N}(7)-\mathrm{H}(71) \cdots \mathrm{O}(10)=$ $3 \cdot 131$ (5) $\AA, 165 \cdot 5(5)^{\circ}$ ] and the imino nitrogen atom $N(11)$ forms a hydrogen bond with $N(15)$ of the symmetry-related molecule $[\mathrm{N}(11)-\mathrm{H}(11) \cdots \mathrm{N}(15)=$ 2.948 (3) $\left.\AA, 149.3(4)^{\circ}\right]$. There is one significantly short intermolecular contact distance of van der Waals type between $\mathrm{O}(9)$ and $\mathrm{N}(15) \quad[\mathrm{O}(9) \cdots \mathrm{N}(15)=$ 2.939 (4) $\AA$ ]. The molecules are stacked together along the diagonals of the $a b$ plane and cross-link each other at the centre of the cell.

The authors thank DST (India) for financial support.

Abstract. $\quad M_{r}=413.47$, monoclinic, $P 2_{1}, \quad a=$ 11.629 (1), $\quad b=11.748$ (1), $\quad c=15.782$ (2) $\AA, \quad \beta=$ $97.23(1)^{\circ}, \quad V=2138.9 \AA^{3}, \quad D_{m}=1.27(1), \quad D_{x}=$ $1.284 \mathrm{~g} \mathrm{~cm}^{-3}, \quad Z=4, \quad \lambda(\mathrm{CuK} \mathrm{\alpha})=1.5418 \AA, \quad \mu=$ $6.12 \mathrm{~cm}^{-1}, F(000)=880, T=293 \mathrm{~K}, R=0.044$ for 2998 reflections. The asymmetric unit of this relatively active colchinoid compound contains two independent molecules which do not differ significantly in bond lengths or angles and the molecular conformations are very similar to each other and to those of previously reported compounds of this type.

Introduction. Colchicine and its analogs are thought to inhibit biological processes by blocking the polymerization of tubulin. While chemical manipulation of colchicine has indicated that aromatic substitution, proper chirality of the acetimido function and a carbonyl group at $\mathrm{C}(9)$ are necessary for effective tubulin binding (Capraro \& Brossi, 1983), definite conclusions as to the role of these functionalities are lacking. The present structure represents the first of a series of investigations of the stereochemical characteristics of both relatively active and relatively inactive colchinoids.

The general formula of the colchinoids is given as (I) and $\quad N$-acetyldemecolcine $\quad(R 1=R 2=R 3=R 4=$ methyl, $R 5=$ acetyl) is a member of the demecolcine © 1985 International Union of Crystallography
