## Structure of Sodium 1,1-Dicyanoethylene-2,2-dithiolate Trihydrate

BY HANS-ULRICH HUMMEL

Institut für Anorganische Chemie der Universität Erlangen-Nürnberg, Egerlandstrasse 1, D-8520 Erlangen, Federal Republic of Germany

(Received 25 March 1986; accepted 31 July 1986)

**Abstract.**  $\text{Na}_2\text{C}_4\text{N}_2\text{S}_2 \cdot 3\text{H}_2\text{O}$ ,  $M_r = 240.21$ , monoclinic,  $I2/m$ ,  $a = 8.750(1)$ ,  $b = 7.588(1)$ ,  $c = 14.479(2)$  Å,  $\beta = 91.00(2)^\circ$ ,  $V = 961.2$  Å $^3$ ,  $Z = 4$ ,  $D_m = 1.70$ ,  $D_x = 1.66$  Mg m $^{-3}$ ,  $\lambda(\text{Ag } K\alpha) = 0.5591$  Å,  $\mu = 0.26$  mm $^{-1}$ ,  $F(000) = 488$ , room temperature,  $R = 0.045$  for 650 observed reflections up to  $(\sin\theta)/\lambda = 0.5527$  Å $^{-1}$ . The 1,1-dicyanoethylene-2,2-dithiolate ligand (dedit) is planar with symmetry  $C_s$ . The structure contains two crystallographically different  $\text{Na}^+$  ions at the centres of distorted octahedra,  $\text{NaO}_2\text{N}_2\text{S}_2$  and  $\text{NaO}_4\text{NS}$ . The water molecules are involved in two approximately linear O—H...S hydrogen bonds (H...S = 2.25 and 2.50 Å) and one O—H...N hydrogen bond (H...N = 1.94 Å).

**Introduction.** This study was stimulated by the fact that the polydentate ligand dedit is thought to be a planar delocalized system while the geometry in the solid state is affected by various intermolecular and packing effects. In the series  $M(\text{dedit}).n\text{H}_2\text{O}$  ( $M = \text{Ca}, \text{Sr}$ ,  $n = 5$ ;  $M = \text{Ba}$ ,  $n = 3$ ) dedit shows considerable deviations

from planarity (Hummel & Wolf, 1985) while in  $\text{K}_2(\text{dedit})\cdot\text{H}_2\text{O}$  the ligand has approximate  $C_{2v}$  symmetry (Hummel, 1985). It might be expected that deviations from planarity of the  $(\text{S}_2\text{C}_4\text{N}_2)^{2-}$  anion should increase with decreasing size of the counterion although this trend is not observed in the series of compounds with alkaline-earth cations.

**Experimental.** Single crystals of  $\text{Na}_2(\text{dedit})\cdot 3\text{H}_2\text{O}$  from ethanol (Söderbäck, 1963). Crystal  $0.08 \times 0.08 \times 0.08$  mm.  $D_m$  determined pycnometrically. Precession photographs. Monoclinic, Laue class  $2/m$ , systematic extinctions  $hkl$ ,  $h + k + l = 2n + 1$ , space group  $I2/m$ . PW 1100 four-circle diffractometer, graphite-monochromatized  $\text{Ag } K\alpha$  radiation,  $\omega$  scan, scan width  $(1.00 + 0.20 \tan\theta)^\circ$ . Cell dimensions based on 25 high-indexed diffractometer-measured intensities ( $7 \leq \theta \leq 12^\circ$ ). 2833 symmetry-dependent reflections ( $-16 \leq h \leq 16$ ,  $-8 \leq k \leq 8$ ,  $-9 \leq l \leq 9$ ;  $2 \leq \theta \leq 18^\circ$ ) averaged to give 722 symmetry-independent reflections,  $R_{\text{int}} = 0.030$ . Three standard reflections, no significant

deviations from their initial intensities. Corrections for Lorentz and polarization effects, no absorption correction applied. Structure solved by direct methods (*MULTAN*, Germain, Main & Woolfson, 1971). 650 observed reflections [ $I > 1.5\sigma(I)$ ] in full-matrix least-squares refinement; 86 parameters; H atoms as parts of rigid  $\text{H}_2\text{O}$  molecules with  $\text{H}\cdots\text{H} = 1.560(5)$  and  $\text{O}-\text{H} = 0.960(5)$  Å, and common isotropic temperature factor;  $\sum w|F_o| - |F_c|^2$  minimized;  $w = 0.1 \times [\sigma^2(F_o) + 7 \times 10^{-4}F_o^2]^{-1}$ ; *SHELX76* system (Sheldrick, 1976);  $(\Delta/\sigma)_{\text{max}} = 0.0091$ ,  $(\Delta/\sigma)_{\text{min}} = 0.001$ ,  $(\Delta/\sigma)_{\text{ave}} = 0.0012$ ;  $\Delta\rho = -0.57$  to  $0.36 \text{ e } \text{\AA}^{-3}$ , correction for empirical isotropic extinction  $F^* = F(1 - 3 \times 10^{-8}F^2/$

$\sin\theta)$ . Final refinement converged to  $R = 0.045$ ,  $wR = 0.043$ ,  $S = 2.1$ . Scattering factors,  $f'$  and  $f''$  from *International Tables for X-ray Crystallography* (1974).

**Discussion.** Final atomic parameters are given in Table 1,\* and selected distances and angles in Table 2. The structure is depicted in Fig. 1. The dedit ions are situated on the mirror planes with  $y = 0, 0.5$  and correspond to approximate  $C_{2v}$  symmetry. All observed intramolecular bond lengths clearly reflect the delocalized  $\pi$  system of dedit (Hummel, 1985). The deviation of the angle C3—C2—C4 from  $120^\circ$  seems to be caused by repulsive forces of the S atoms and is observed in many other salts of dedit (Hummel & Wolf, 1985). There are two crystallographically different sodium ions in the

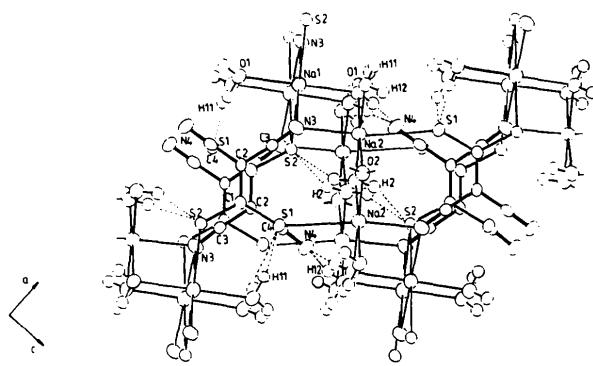

Fig. 1. A projection of  $\text{Na}_2\text{S}_2\text{C}_4\text{N}_2\cdot 3\text{H}_2\text{O}$  on the  $ac$  plane. The dedit anions are situated on mirror planes with  $y = 0.0$  and  $0.5$ .

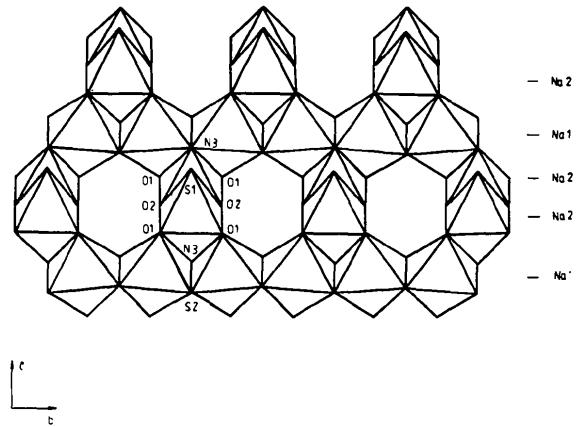

Fig. 2. The polyhedron layer in  $\text{Na}_2\text{(dedit)}\cdot 3\text{H}_2\text{O}$ .

structure; Na1 with site symmetry  $\bar{1}$  and Na2 on  $m$ . Na1 is surrounded by two S, two N and two water O atoms forming a distorted octahedron. These polyhedra share edges N3–S2 forming chains  $\text{[NaO}_2\text{N}_{2/2}\text{S}_{2/2}]$  parallel to [010]. Each dedit links two different chains via the *trans*-positioned S2 and N3 atoms. Na2 coordinates four water O atoms ( $2 \times \text{O}1, 2 \times \text{O}2$ ), one S1 and one N3 atom. Na2 polyhedra form pairs by edge-sharing [ $\text{O}(2)\text{—O}(2)$ ] and these pairs are connected with the Na1 octahedra via common O1 and N3 atoms (Fig. 2).

As a result, short and long O1–O1 distances alternate along [010]. The Na–O and Na–N distances correspond to usually observed bond lengths (Colapietro, Domenicano & Vaciago, 1968). A sodium–sulfur coordination is mainly found in inorganic compounds with Na–S distances in the range 2.8–3.1 Å (Mereiter, Preisinger & Guth, 1979).

There are two crystallographically different water molecules (site symmetries 1 and 2) interspersed between the layers of dedit ions which build up a symmetric set of hydrogen bonds with respect to the mirror planes. The molecule  $\text{H}_2\text{O}(1)$  connects two dedit ions in  $y = 0$  and  $y = 0.5$  via an unusually short S...H contact ( $\text{S}1\cdots\text{H}11 = 2.25$  Å) and an N–H hydrogen bridge ( $\text{N}4\cdots\text{H}12 = 1.94$  Å), while  $\text{H}_2\text{O}(2)$  is associated with two anions within the same layer ( $y = 0$  or  $0.5$ ) via  $\text{H}2\cdots\text{S}2$  contacts with  $\text{H}\cdots\text{S} = 2.50$  Å. The distances  $\text{O}\cdots\text{X}$  ( $\text{X} = \text{S}2, \text{N}4$ ) are in the range given by Kuleshova & Zorkii (1981) and Chiari & Ferraris (1982) while the  $\text{O}1\cdots\text{S}1$  distance is at the low end of usually observed values (3.23–3.31 Å).

It is expected that hydrogen bonds as well as the charge and size of a metal cation in the salts of dedit (Table 3) will lead to deviations from planarity of the ligand. Nevertheless no systematic trend within the

Table 3. Maximum deviations from planarity of dedit in some ionic compounds (Å)

Compound	$\Delta$	Reference
$\text{Ba}(\text{dedit})\cdot 3\text{H}_2\text{O}$	0.10	Hummel & Wolf (1985)
$\text{Sr}(\text{dedit})\cdot 5\text{H}_2\text{O}$	0.04	Hummel & Wolf (1986)
$\text{Ca}(\text{dedit})\cdot 5\text{H}_2\text{O}$	0.10	Wolf & Hummel (1985)
$\text{K}_2(\text{dedit})\cdot \text{H}_2\text{O}$	0.03	Hummel (1985)

known compounds is observed. Although the metal cation in the present species is small ( $r_{\text{Na}^+} = 0.97$ ,  $r_{\text{Ba}^{2+}} = 1.34$  Å; Shannon & Prewitt, 1969), dedit is situated on a mirror plane and forms an effective and symmetric set of hydrogen bonds.
