

## Dibenzyl[1,2-bis(dimethylphosphino)ethane]bis(cyclopentadienyl)thorium(IV)

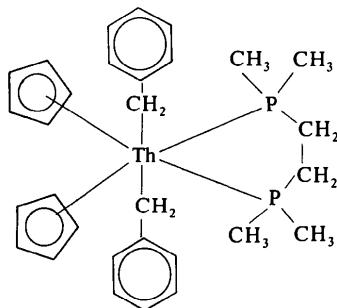

BY ALLAN ZALKIN, JOHN G. BRENNAN AND RICHARD A. ANDERSEN

*Materials and Molecular Research Division, Lawrence Berkeley Laboratory and Department of Chemistry,  
University of California, Berkeley CA 94720, USA*

(Received 13 June 1986; accepted 16 September 1986)

**Abstract.**  $[\text{Th}(\text{C}_5\text{H}_5)_2(\text{C}_7\text{H}_7)_2(\text{C}_6\text{H}_{16}\text{P}_2)]$ ,  $M_r = 694.64$ , triclinic,  $P\bar{1}$ ,  $a = 13.104$  (4),  $b = 11.124$  (4),  $c = 10.518$  (4) Å,  $\alpha = 89.90$  (3),  $\beta = 92.99$  (3),  $\gamma = 110.16$  (3)°,  $V = 1437.1$  Å<sup>3</sup>,  $Z = 2$ ,  $D_x = 1.605$  g cm<sup>-3</sup>,  $\lambda(\text{Cu } K\alpha) = 1.5418$  Å,  $\mu = 179.1$  cm<sup>-1</sup>,  $F(000) = 680$ ,  $T = 296$  K,  $R = 0.028$  for 4021 unique reflections with  $F^2 > \sigma(F^2)$  of 4279 total unique data. Distances (Å) are: ave. Th–C(Cp) 2.83 ± 0.05; Th–C(benzyl) 2.648 (6), 2.666 (7); Th–P 3.142 (2), 3.237 (2); Th–Cp(ring) 2.56, 2.59. The cyclopentadienyl rings are *trans* to the bidentate ligand, in agreement with Keppert's rules for six-coordinate complexes. There are no interactions between the Th atom and the aryl ring.

**Introduction.** In the preceding paper (Zalkin, Brennan & Andersen, 1987) the X-ray crystal structures of  $(\text{C}_5\text{H}_5)_2\text{Th}(X)_2(\text{CH}_3)_2\text{PCH}_2\text{CH}_2\text{P}(\text{CH}_3)_2$ , where  $X = \text{CH}_3$  or Cl, were described and the geometry of the complexes was rationalized on the basis of Keppert's rules (Keppert, 1977). In our synthetic studies we prepared the benzyl analogue,  $X = (\text{CH}_2\text{C}_6\text{H}_5)_2$ , the structure of which is of considerable interest since the benzylic group often behaves as an  $\eta^3$ - or  $\eta^4$ -benzylic ligand towards actinide centers, e.g. *ortho*- and *ipso*-carbon–uranium distances are shorter than the sum of the van der Waals radii of the elements (Mintz, Moloy, Marks & Day, 1982; Edwards, Andersen & Zalkin, 1984).

**Experimental.** The complex was made by the reaction of  $[\text{Th}(\text{C}_5\text{H}_5)_2\text{Cl}_2(\text{C}_6\text{H}_{16}\text{P}_2)]$  with benzyllithium at 228 K (Brennan, 1985). Crystals suitable for the X-ray

study were grown from a toluene:pentane (1:1) mixture at 203 K. Yellow air-sensitive crystals were sealed inside quartz capillaries under argon. Crystal 0.18 × 0.19 × 0.25 mm with six faces; modified Picker automatic diffractometer, graphite monochromator; cell dimensions from 36 reflections,  $40 < 2\theta < 80$ °; analytical absorption correction, range 5.39 to 20.85; max.  $(\sin\theta)/\lambda = 0.56$  Å<sup>-1</sup>;  $h = -13$  to 13,  $k = 0$  to 12,  $l = -11$  to 11; three standard reflections, average decay 5%, intensities adjusted accordingly; 6932 data, 4279 unique,  $R_{\text{int}} = 0.030$ ; structure solved by Patterson and Fourier methods; refined on  $F$ ,  $f'$  and  $f''$  terms included, 394 parameters; positional coordinates of all the hydrogen atoms were estimated and, with the exception of the 16 dimethylphosphinoethane hydrogen atoms, were refined in the least-squares refinements with isotropic thermal parameters; dimethylphosphinoethane H-atom parameters included but not refined; anisotropic thermal parameters for non-hydrogen atoms; large anisotropies in the thermal parameters of C(27) and C(28) and a short C–C bond length suggest disorder in the dimethylphosphinoethane ligand,  $R = 0.031$  for 4279 data;  $R = 0.028$  for 4021 reflections for which  $F^2 > \sigma(F^2)$ ;  $wR = 0.033$ ;  $S = 1.3$ ;  $w = [\sigma(F)]^{-2}$ ,  $p = 0.045$  in calculation of  $\sigma(F^2)$ ; max.  $(\text{shift}/\sigma) < 0.04$ ; empirical extinction correction,  $F_{\text{corr}} = (1 + kI)$ ,  $k = 2.3 \times 10^{-7}$ ; max. and min. of  $\Delta F$  synthesis 1.3 and -1.1 e Å<sup>-3</sup>; atomic  $f$ ,  $f'$  and  $f''$  for neutral Th, Cl, P and C, and spherical bonded H from International Tables for X-ray Crystallography (1974); local unpublished programs and ORTEP (Johnson, 1965).

Atomic parameters are listed in Table 1,\* and distances and angles are listed in Table 2. Fig. 1 shows the molecule and numbering scheme.

**Discussion.** The stereochemistry of the title compound is similar to that of the methyl and chloro analogues

\* Lists of structure factors, anisotropic thermal parameters, calculated hydrogen positions, distances and angles, and least-squares planes have been deposited with the British Library Document Supply Centre as Supplementary Publication No. SUP 43410 (24 pp.). Copies may be obtained through The Executive Secretary, International Union of Crystallography, 5 Abbey Square, Chester CH1 2HU, England.

\* Atoms refined isotropically.

(Zalkin, Brennan & Andersen, 1987). This is expected on the bases of Keppert's rules (Keppert, 1977) since a Th–ring centroid distance of 2.57 Å is less than the averaged Th–C(benzyl) bond distance of 2.657 (5) Å, and the ligand with the shortest metal–ligand bond will prefer to occupy the site *trans* to the bidentate ligand. The averaged Th–C(benzyl) distance is longer than the equivalent Th–C(CH<sub>3</sub>) distance in the methyl analogue of 2.573 (6) Å (Zalkin, Brennan & Andersen, 1987). This is consistent with previous structural results which show that the uranium or thorium benzyl bond length is *ca* 0.1 Å longer than the equivalent metal–carbon (sp<sup>3</sup>-hybridized) distance (Perego, Cesari, Farina &

\* Cp(1) and Cp(2) represent the centroids of cyclopentadienyl atoms C(1)–C(5) and C(6)–C(10) respectively.

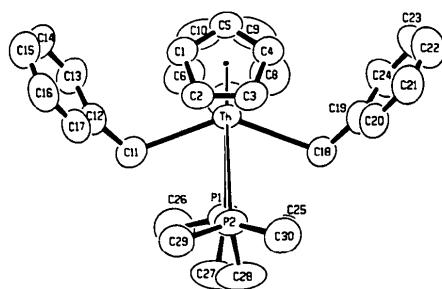

Fig. 1. ORTEP (Johnson, 1965) view of the title compound showing the atomic numbering scheme; 50% probability ellipsoids.

Lugli, 1976; Edwards, Andersen & Zalkin, 1984).

The two independent Th–P distances are significantly different, with an averaged distance of 3.19 (3) Å. The Th–P distance is substantially longer than that found in the chloro [3.122 (1) Å] and methyl [3.147 (1) Å] analogues (Zalkin, Brennan & Andersen, 1987). In all three complexes the averaged Th–C(C<sub>5</sub>H<sub>5</sub>) distances are equal within experimental error. The long Th–P distances can be rationalized most easily as a steric effect since the benzyl group is larger than a methyl group which prevents the phosphine from getting closer to the thorium atom in the benzyl derivative.

The principal reason for investigating the structure of the benzyl derivative was to examine the interaction, if any, between the actinide metal center and the aryl-ring carbon atoms. There are no thorium–carbon contacts shorter than 3.2 Å and the Th–C(18)–C(19), Th–C(11)–C(12) angles are normal. This is consistent with the explanation advanced previously (Edwards, Andersen & Zalkin, 1984) which suggested that the η<sup>3</sup>- or η<sup>4</sup>-benzylic interactions are relatively weak (on the

order of solvation energies or crystal packing energies) and that they are a manifestation of the desire of the large electropositive actinide metals to maximize their coordination numbers and to minimize the intramolecular ligand-ligand repulsions. The molecular structure is a compromise between these two conflicting tendencies. In the molecule described here, the thorium atom is coordinatively saturated and no benzylic interactions are observed.
