#### Abstract

Co}\left(\mathrm{C}_{10} \mathrm{H}_{9} \mathrm{~N}_{3}\right)_{2}\left(\mathrm{CO}_{3}\right)\right] \mathrm{ClO}_{4}, \quad M_{r}=560.8\), monoclinic, $P 2_{1} / n, \quad a=10.983$ (3), $\quad b=13.640$ (2), $c=15.548$ (3) $\AA, \quad \beta=93 \cdot 23$ (1) ${ }^{\circ}, \quad V=2325.5$ (9) $\AA^{3}$, $Z=4, D_{m}=1.62(1), D_{x}=1.60 \mathrm{Mg} \mathrm{m}^{-3}$, Мо $K \alpha, \lambda$ $=0.71069 \AA, \mu=0.904 \mathrm{~mm}^{-1}, F(000)=1144$, room temperature, $R=0.094$ for 2039 reflections. The cation possesses a pseudo-octahedral structure with a bidentate carbonato ligand. The bond lengths and angles are normal, but some short non-bonded distances suggest interligand repulsion. Hydrogen bonds occur between the secondary amine groups and (i) the carbonate ligand of a neighbouring cation and (ii) the partially disordered perchlorate anion.

Introduction. The bidentate ligand di-2-pyridylamine [dipyam, (1)] is unusual in forming an $\eta^{2}$ dioxygen complex $\left[\mathrm{Co}(\text { dipyam })_{2} \mathrm{O}_{2}\right]^{+}$on treatment with hydrogen peroxide (Johnson \& Geldard, 1978). An attempt to grow crystals containing this complex yielded the perchlorate salt of the carbonato complex. The crystal structure of this compound is reported, and allows comparison of the structural properties of the ligand dipyam with the analogous $2,2^{\prime}$-bipyridyl [bpy, (2)] and 1,10 -phenanthroline [phen, (3)] cobalt (III) carbonato complexes (Niederhoffer, Martell, Rudolf \& Clearfield, 1982).

0108-2701/87/050883-03\$01.50

Experimental. Preparation of crystals: di-2-pyridylamine (previously recrystallized from ethanol), 0.54 g , and cobalt(II) perchlorate hexahydrate, 0.36 g , were dissolved in 150 ml of ethanol:water (2:1) and filtered into a clean flask. 7 ml of $30 \%$ hydrogen peroxide were added, and the flask placed in a dewar filled with warm water at 323 K . Over a period of four weeks, red crystals were slowly deposited. Density was measured by flotation.

A parallelepiped $0.18 \times 0.15 \times 0.30 \mathrm{~mm}$ was measured using a Philips PW 1100 diffractometer, $\omega / 2 \theta$ scan, scan width $1 \cdot 1^{\circ}$, scan speed $1 \cdot 8^{\circ} \mathrm{min}^{-1}$. Graphite-monochromated Mo $\mathrm{K} \mathrm{\alpha}$ radiation. 3123 reflections measured $\left(6<2 \theta<44^{\circ} ; h=-11, \quad 11 ;\right.$ $k=0,14 ; l=0,16$ ). 2717 unique reflections ( $R_{\text {int }}$ $=0.017$ ) of which 649 were taken as unobserved $\left[\left|F_{o}\right| \leq 4 \sigma\left(F_{o}\right)\right.$ and $\left.\left|F_{o}\right| \leq 8.0\right]$. Two standard reflections measured every 90 min showed a variation of less than $1 \cdot 8 \sigma(I)$, and no correction for change in intensity was applied. Cell parameters from least-squares refinement of 30 centred reflections ( $19 \leq 2 \theta \leq 30^{\circ}$ ). Data corrected for Lorentz and polarization effects but not for absorption. The structure was solved by direct methods using MULTAN80 (Main, Fiske, Hull, Lessinger, Germain, Declercq \& Woolfson, 1980). All other calculations used a local version of XRAY76 (Stewart, Machin, Dickinson, Ammon, Heck \& Flack, 1976) and ORTEPII (Johnson, 1976). Scattering factors from International Tables for X-ray Crystallography (1974). Least-squares refinement on $|F|$ (block matrix, four blocks) with all H atoms in calculated positions gave final values $R=0.094, w R=0.135, S=3.08$ for 2039 reflections with $w=1$ for $\left|F_{o}\right| \leq 48, w=\left(48 /\left|F_{o}\right|\right)^{2}$ for $\left|F_{o}\right|>48$. $(\Delta / \sigma)_{\max }=0.931$. The final difference © 1987 International Union of Crystallography

Fourier map showed max. and min. of +0.79 and $-0.81 \mathrm{e}^{\AA} \mathrm{A}^{-3}$.

Discussion. Atomic coordinates and equivalent isotropic temperature factors are given in Table 1, and selected bond lengths, bond angles and short nonbonded distances in Table 2.* Fig. 1 shows the atom numbering and Fig. 2 is a stereoview of the cation.
The cation shows pseudo-octahedral coordination of the cobalt as expected for a complex with three bidentate ligands. There is an approximate twofold axis of symmetry running through $\mathrm{Co}, \mathrm{C}(21)$ and $\mathrm{O}(3)$.
The bond lengths and angles of the complexed carbonato ligand are normal and similar to those for the analogous bpy and phen complexes (Niederhoffer et al., 1982). The average $\mathrm{Co}-\mathrm{N}$ bond length [ $1.932(10) \AA$ ] is identical, within experimental error, to

those found with bpy and phen, but the chelate bite angles $[\mathrm{N}(2)-\mathrm{Co}-\mathrm{N}(3) \quad 88.6$ (4); $\mathrm{N}(5)-\mathrm{Co}-\mathrm{N}(6)$ $\left.89.0(4)^{\circ}\right]$ are greater than for bpy [83.2(2) ${ }^{\circ}$ ] and phen $\left[84.3(3)^{\circ}\right]$, and are closer to the value of $90^{\circ}$ expected for an ideal octahedron. The greater bite angle presumably arises from the six-membered chelate ring in the dipyam complex.

Fig. 1. Line drawing of $\left[\mathrm{Co}(\text { dipyam })_{2} \mathrm{CO}_{3}\right]^{+}$showing numbering of atoms. The perchlorate anion [atoms Cl and $\mathrm{O}(4)$ to $\mathrm{O}(7)$ ] is omitted.

Fig. 2. Stereoview of the cation $\left[\mathrm{Co}(\text { dipyam })_{2} \mathrm{CO}_{3}\right]^{+}$.

In contrast to bpy and phen, the dipyam ligand is strongly distorted from planarity. The angles between the least-squares planes through the two pyridyl rings of each ligand are $36 \cdot 1$ (5) and 37.4 (5) ${ }^{\circ}$ for the two independent dipyam molecules in the complex. These values are similar to those found for dipyam bound to $\mathrm{Cu}^{\text {II }}$ (Fuller \& Jacobson, 1981; Jensen \& Jacobson, 1981) and $\mathrm{Pd}^{11}$ (Freeman \& Snow, 1965). The axis of intersection of the two least-squares planes passes close to the Co atom and the secondary amine N atom, the amine N atom lying in the obtuse and the Co atom in the reflex angle formed by the two planes. The six-membered chelate ring has a boat conformation, and the $\mathrm{Co}-\mathrm{N}$ bond makes an average angle of $11.5^{\circ}$ with the plane of the pyridyl ring.

The unusually intense transitions in the electronic spectrum of $\left[\mathrm{Co}(\text { dipyam })_{3}\right]^{3+}$ are thought to arise from ligand-ligand repulsions (Johnson \& Geldard, 1979). In the cation $\left.[\mathrm{Co} \text { (dipyam) })_{2}\left(\mathrm{CO}_{3}\right)\right]^{+}$, all the C atoms in the 6 -position of the pyridyl rings show some interaction with the other dipyam molecule as shown by short non-bonded distances ( $\mathrm{C}-\mathrm{C}$ or $\mathrm{C}-\mathrm{N}$ distances less than $3.2 \AA$, Table 2 ). For the bpy and phen complexes, in contrast, such short interligand distances are found only between the two mutually cis pyridyl groups trans to the carbonate. This supports the hypothesis of greater interligand repulsion in complexes of dipyam, and may be attributed to the expansion of the chelate ring which moves the C atoms in the 6 -position closer to the centre of the complexes and thus nearer to the other ligands.

The H atoms of the secondary amine groups are involved in hydrogen bonding. One is hydrogen bonded
to the terminal O atom of the carbonate of another cation [distance $\mathrm{N}(4) \cdots \mathrm{O}(3)(-x,-y, \quad 2-z)=$ 3.018 (12) $\AA$ ]. The other is hydrogen bonded to an O atom of the perchlorate anion [distance $\mathrm{N}(1) \cdots \mathrm{O}(7)$ $(1-x, 1-y, 2-z)=3.088(14) \AA]$. The other O atoms of the perchlorate anion show much larger atomic displacement parameters, and may be considered as disordered, and this is presumably responsible for the relatively high final $R$ factor.

#### Abstract

CrF}_{2}\left(\mathrm{C}_{2} \mathrm{H}_{8} \mathrm{~N}_{2}\right)_{2}\right] \mathrm{ClO}_{4}, \quad M_{r}=309.65\), monoclinic, $P 2_{1} / c, a=5.587$ (1), $b=11.601$ (2), $c$ $=17.774$ (3) $\AA, \quad \beta=98.07(1)^{\circ}, \quad V=1140.6$ (6) $\AA^{3}$, $Z=4, \quad D_{m}=1.80(1), \quad D_{x}=1.803 \mathrm{Mg} \mathrm{m}^{-3}, \quad$ Mo $K \alpha$, $\lambda=0.71069 \AA, \quad \mu=1.19 \mathrm{~mm}^{-1}, \quad F(000)=636, \quad T=$ $293 \mathrm{~K}, R=0.052$ for 1569 reflections. The Cr atom is in an octahedral environment coordinated by two bidentate ethylenediamines and two F atoms in a cis position. Cations are in the $\Lambda \delta \lambda$ and $\Delta \lambda \delta$ enantiomeric

forms. $\mathrm{Cr}-\mathrm{F}$ and $\mathrm{Cr}-\mathrm{N}$ bonds are 1.883 (3), 1.882 (3); and from 2.072 (4) to 2.099 (4) $\AA$. Weak $\mathrm{N} \cdots \mathrm{F}$ hydrogen bonds exist between cations.

Introduction. Structural studies of fluoro-containing chromium(III) coordination compounds are rare. $\left[\mathrm{CrF}_{2}(\mathrm{en})_{2}\right]^{+}$(en $=\mathrm{NH}_{2}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{NH}_{2}$ ) can exist as trans and cis isomers. Structures of trans- $\left[\mathrm{CrF}_{2}-\right.$ (en) $\left.)_{2}\right]_{C l O}^{4}$ and trans- $\left.-\mathrm{CrF}_{2}(\mathrm{en})_{2}\right] \mathrm{Cl}$ were solved
