Structure of Tetracarbonyl[tris(trimethylsilyl)phosphine]iron(0)

BY ANDREW R. BARRON, ALAN H. COWLEY* AND CHRISTINE M. NUNN

Department of Chemistry, The University of Texas at Austin, Austin, Texas 78712, USA

(Received 24 August 1987; accepted 4 December 1987)

Abstract. $[\text{Fe}(\{\text{CH}_3)_3\text{Si}\}_3\text{P}](\text{CO})_4$, $M_r = 418.4$, monoclinic, Cc , $a = 9.548$ (2), $b = 15.052$ (3), $c = 15.552$ (6) Å, $\beta = 98.12$ (2)°, $V = 2212.7$ Å³, $Z = 4$, $D_x = 1.256$ Mg m⁻³, $\lambda(\text{Mo K}\alpha) = 0.71073$ Å, $\mu = 0.921$ mm⁻¹, $F(000) = 880$, $T = 296$ (1) K, final $R = 0.0590$ for 1204 unique observed diffractometer data and 199 variables. Coordination about Fe is trigonal bipyramidal with the phosphine occupying an axial site and an Fe–P bond length of 2.338 (4) Å.

Experimental. Title compound prepared according to the literature method (Schumann & Stelzer, 1968). Orange crystals from toluene on cooling to 278 K. Crystals mounted under argon in thin-walled glass capillaries. A prism with dimensions 0.24 × 0.33 × 0.62 mm used for X-ray work. Lattice parameters determined by least-squares fitting of setting angles of reflections, $12 < \theta < 15$ °, automatically centred on CAD-4 diffractometer. Intensities collected with graphite-monochromated Mo K α radiation, $\lambda = 0.71073$ Å, $\omega/2\theta$ scan mode, scan width (0.8 + 0.35tanθ)°, aperture setting 4 mm, $1.5 \leq \theta \leq 25$ °, 2163 reflections measured, 2076 unique, 842 unobserved [$I \geq 3\sigma(I)$], index range $0 \leq h \leq 11$, $0 \leq k \leq 17$, $-18 \leq l \leq 18$ where $h + k = 2n$. Two intensity control reflections, monitored after every hour of data collection, showed only slight variation; Lorentz–polarization correction and absorption correction *via* ψ scans, max. = 99.55, min. = 77.12%. No extinction correction was applied. Structure was solved by Patterson synthesis. Full-matrix least-squares anisotropic refinement of positions of non-hydrogen atoms (no H's were refined). A non-Poisson-contribution weighting scheme was used with an experimental instability factor of $P = 0.06$ used in the calculation of $\sigma(I)$ to downweight intense reflections. The function $\sum w(|F_o| - |F_c|)^2$ was minimized where $w = 4(F_o)^2/[\sum(F_o)^2]^2$, where $[\sum(F_o)^2]^2$

Anisotropically refined atoms are given in the form of the isotropic equivalent thermal parameter defined as $\frac{4}{3}[a^2B(1,1) + b^2B(2,2) + c^2B(3,3) + ab\cos\gamma B(1,2) + ac\cos\beta B(1,3) + bc\cos\alpha B(2,3)]$.

Structure of Di[bis(triphenylphosphine)iminium] Hexachlororhenate(IV)

BY CHUNG-NIN CHAU, ROBERT W. M. WARDLE AND JAMES A. IBERS

Department of Chemistry, Northwestern University, Evanston, Illinois 60208, USA

(Received 14 October 1987; accepted 25 November 1987)

Abstract. [(C₆H₅)₃NNP(C₆H₅)₃]₂[ReCl₆]₂, $M_r = 1476 \cdot 1$, orthorhombic, *Pbca* (D_{2h}^{15}), $a = 16.59$ (1), $b = 19.49$ (1), $c = 19.88$ (1) Å, $V = 6428$ (3) Å³, $Z = 4$, $D_x = 1.53$ g cm⁻³, Mo $K\alpha$, $\lambda(K\alpha_1) = 0.7093$ Å, $\mu = 23.1$ cm⁻¹, $F(000) = 2970$ (including anomalous dispersion), $T = 123$ K, $R(F^2) = 0.109$ for 4127 independent reflections. The ReCl₆²⁻ anion has crystallographically imposed symmetry $\bar{1}$, the Re–Cl distances are 2.351 (3), 2.355 (3) and 2.376 (3) Å, and

the Cl–Re–Cl angles are 89.72 (11), 91.10 (10) and 91.23 (10)°.

Experimental. Dark yellowish-green crystals of bis(triphenylphosphine)iminium hexachlororhenate, [PPN]₂[ReCl₆]₂, were obtained by combining 0.5 g rhenium pentachloride, 0.1 g rhenium powder, 0.2 g selenium powder, and 1.0 g [PPN]Cl with 1.0 g bis(dimethyloctylsilyl) selenide (Chau, Wardle & Ibers,
