

represents the configuration of the complex cation together with the atom-labelling sequence. The central Cu²⁺ ion binds the NCS⁻ ion and the two bipy ligands via the N atoms, so that N(1), N(13) and N(25) are located in the equatorial plane of the trigonal bipyramidal with the Cu²⁺ ion almost in this plane [max. deviation 0.023 (1) Å; N(12) and N(24) occupy axial sites, with N(12)-Cu-N(24) = 176.4 (1)°]. The three equatorial N-Cu-N bond angles are close to 120° (Table 2), so that the distortion from a regular trigonal bipyramidal is very small compared with the distortion found in the monoclinic [Cu(bipy)₂NSC]BF₄ complex (Tyagi & Hathaway, 1981). In the tetrafluoroborate salt of the complex, the two Cu-N(bipy) equatorial distances are significantly different, which is not so in the present case (Table 2). There are no unusual bond lengths and bond angles in the bipy ligands. The individual pyridine rings are planar [max. deviation 0.011 (4) Å] and the pertinent dihedral angles for each bipy ligand are 5.4 and 7.1° (corresponding to 0.6 and 3.2° in the monoclinic analogous complex). The dihedral angle between the mean planes of the bipy ligands is 64.0°, which is significantly smaller than the value of 100.1° in the analogous complex. There is nothing unusual in the NCS⁻ ligand (Stults, Day, Marianelli & Day, 1979), but the Cu-N(25)-C(26) angle has the value of

166.2 (2)° compared with 174.2 (5)° in the analogous complex.

The crystal packing is achieved with the uncoordinated nitrate ions and water molecules. There are no short intermolecular interactions that could correspond to hydrogen bonds.

Abstract. [RuCl₂(CO)₂(C₁₄H₁₀N₄)]. (1) $M_r = 462.3$, monoclinic, $P2_1/c$, $a = 15.004$ (2), $b = 10.641$ (1), $c = 10.849$ (1) Å, $\beta = 94.31$ (1)°, $V = 1727.3$ (4) Å³, $Z = 4$, $D_x = 1.777$ g cm⁻³, Mo K α , $\lambda = 0.71069$ Å, $\mu = 12.2$ cm⁻¹, $F(000) = 912$, $T = 298$ K, final conventional $R = 0.029$ for 2054 unique observed reflections. (2) $M_r = 462.3$, monoclinic, $P2_1/c$, $a = 7.152$ (1), $b = 16.439$ (2), $c = 14.708$ (2) Å, $\beta = 93.46$ (1)°, $V = 1726.0$ (4) Å³, $Z = 4$, $D_x = 1.779$ g cm⁻³, Mo K α , $\lambda = 0.71069$ Å, $\mu = 12.2$ cm⁻¹, $F(000) = 912$, $T = 298$ K, final conventional $R = 0.023$ for 2751 unique observed reflections. Both (1) and (2) have a six-coordinated Ru atom with a distorted

octahedral geometry, being bonded by two N atoms of the organic ligand, which acts as bidentate, by two Cl atoms and by two C atoms of CO groups. In (1) the Cl atoms are in *trans* position, the CO groups being *cis*; in (2) both Cl and CO groups are in *cis* position.

Introduction. Mono- and dinuclear ruthenium(II) complexes of chelating (Cole-Hamilton, 1980; Deacon, Patrick, Skelton, Thomas & White, 1984) and bis-chelating (Braunstein, Baker, Strekas & Gafney, 1984; Ruminski & Petersen, 1982) heterocyclic N-donor ligands are receiving much attention in view of their interesting photocatalytic properties. Among the ligands

of the above class, 3,6-bis(2-pyridyl)pyridazine (bppi) has been used to synthesize several mono- and bimetallic complexes, and the X-ray structures of some of them have been determined by us (Manotti Lanfredi, Tiripicchio, Ghedini & De Munno, 1982; De Munno, Denti & Dapporto, 1983; De Munno & Denti, 1984; De Munno & Bruno, 1984). We report here on two mononuclear isomeric species in which bppi chelates the Ru(CO)₂Cl₂ moiety.

Experimental. From a light-protected methanolic suspension of Ru(CO)₂Cl₂ and bppi in the molar ratio 1:1, a pale yellow microcrystalline precipitate of [Ru(bppi)-(CO)₂Cl₂] (1) was recovered. The X-ray structural analysis showed that (1) was the *cis*-dicarbonyl-*trans*-dichloro species. The *cis*-dicarbonyl-*cis*-dichloro species was prepared from a warm acetonitrile solution of the dinuclear (μ -bppi) [Ru(CO)₂Cl₂]₂ (Denti, De Rosa & Stillitani, 1987) compound. On cooling a gold-yellow microcrystalline compound was recovered. Crystals suitable for X-ray measurements were obtained from a warm ethanolic or acetonitrile solution for (1) and (2) respectively. Crystals 0.12 × 0.12 × 0.18 (1), 0.15 × 0.15 × 0.18 mm (2). Siemens-Stoe diffractometer, scan range $2\theta = 3-52^\circ$, graphite-monochromatized Mo K α radiation, $\omega-2\theta$ scan technique. 20 reflections with $16 < 2\theta < 30^\circ$ (1) and $14 < 2\theta < 24^\circ$ (2) used for measuring lattice parameters. No systematic loss of intensity of three standard reflections measured [113, 161, 161 for (1); and 340, 341, 454 for (2)]. 3398 reflections measured with $\theta < 26^\circ$, 2054 unique with $I \geq 3\sigma(I)$, $0 \leq h \leq 14$, $0 \leq k \leq 14$, $-19 \leq l \leq 19$ for (1). 3344 reflections measured with $\theta < 26^\circ$, 2751 unique with $I > 3\sigma(I)$, $-18 \leq h \leq 18$, $-20 \leq k \leq 0$, $0 \leq l \leq 9$ for (2). R_{int} (from merging equivalent reflections) 0.018 and 0.014 for (1) and (2) respectively. Absorption ignored. Lp corrections. Scattering factors for non-hydrogen atoms from *International Tables for X-ray Crystallography* (1974, p. 99) and for H atoms from Stewart, Davidson & Simpson (1965). Anomalous-dispersion corrections from *International Tables for X-ray Crystallography* (1974, p. 149). Structures solved by Patterson and Fourier techniques and refined by a full-matrix least-squares procedure; $\sum w(|F_o| - |F_c|)^2$ minimized; anisotropic thermal parameters for Ru, C, N, Cl and O, H atoms (calculated) assigned isotropic U of 0.06 Å² and not refined; final $R = 0.029$, $wR = 0.034$, $w = 0.5480/[\sigma^2(F_o) + 0.002108(F_o)^2]$; $S = 0.77$, max. $\Delta/\sigma = 0.01$, max. and min. $\Delta\rho$ excursions in ΔF synthesis 0.49 and -0.11 e Å⁻³ for (1). Final $R = 0.023$, $wR = 0.028$, $w = 0.3777/[\sigma^2(F_o) + 0.002057(F_o)^2]$; $S = 0.77$, max. $\Delta/\sigma = -0.13$, max. and min. $\Delta\rho$ excursions in ΔF synthesis 0.34 and -0.52 e Å⁻³ for (2). VAX/VMS computer of the Università della Calabria and IBM 4341 computer of the Università di Messina; *SHELX* (Sheldrick, 1976) and *PARS* programs (Nardelli, 1983). Final atomic

Discussion. Complexes (1) and (2) consist of Ru^{II} atoms, surrounded in an octahedral arrangement by two Cl atoms, two CO groups and two N atoms of the bppi ligand, which acts as bidentate, the non-coordinating N atoms being mutually *trans*. In both complexes the N atom of the coordinated pyridine ring is on

the opposite side with respect to a CO group, whereas in (2) a Cl atom is on the opposite side with respect to a pyridazine N atom, in (1) to a CO group. Assuming that the coordinated N atoms of the ligand occupy the equatorial positions of the octahedron, the axial positions are occupied in (1) by a Cl atom and a CO group, in (2) by two Cl atoms. The bite angle of the ligand is 77.1 (1) and 78.3 (1)° for (1) and (2) respectively. The pyridazine ring forms a different dihedral angle with the pyridine ring (*a*) involved or (*b*) not involved in the chelation. In the *cis*-*cis* compound (*a*) is greater and (*b*) is smaller than in the *cis*-*trans* one, the values being 8.9 (1) vs 4.9 (1)° and 5.6 (1) vs 13.0 (1)° respectively. The relevant difference of (*b*) dihedral angles might be caused by increased steric interactions between the rings in the *cis*-*trans* isomer with respect to the *cis*-*cis* one. The C—C inter-ring distance for the pyridazine-pyridine uncoordinated ring is longer in the *cis*-*cis* species than in the *cis*-*trans* one [1.490 (4) instead of 1.475 (6) Å]. All C—C and C—N distances in the ligand are almost in the same range for (1) and (2) and similar to those previously reported for bppi (Manotti Lanfredi, Tiripicchio, Ghedini & De Munno, 1982; De Munno Denti & Dapporto, 1983; De Munno & Denti, 1984). If we consider as the equatorial plane of the octahedron the Ru—N(2)—N(1)—C(15)—C(16) and Ru—N(2)—N(1)—C(15)—Cl(1) average planes for the *cis*-*trans* and the *cis*-*cis* isomers respectively, we observe a shortening of the Ru—N(2) distance [2.084 (3) and 2.049 (2) Å for (1) and (2)], whereas Ru—Cl(1) increases from 2.392 (1) to 2.431 (1) Å. The Ru—N(2) distance is longer for (1) (*cis*-*trans*) than for (2) (*cis*-*cis*). In the first case the N

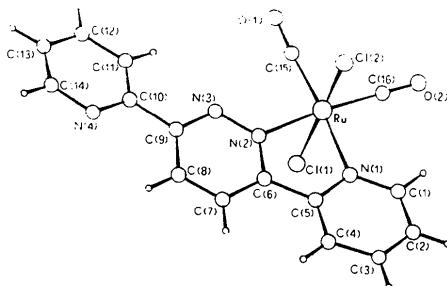

Fig. 1. Molecular structure and atom-labeling scheme for (1).

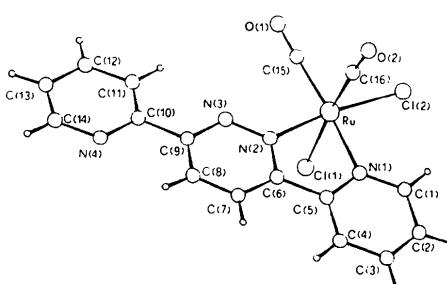

Fig. 2. Molecular structure and atom-labeling scheme for (2).

atom is *trans* to a CO group, in the second it is *trans* to a Cl atom. A similar behaviour is observed for the Ru—Cl(1) distance, which is longer in (2) than in (1). In (2) the Cl atom is *trans* to a CO group, whereas in (1) it is *trans* to Cl. It is in accordance with the expected *trans* influence order and with that previously reported for *cis*-bis(2,2'-bipyridyl)carbonylchlororuthenium(II) perchlorate (Clear, Kelly, O'Connell, Vos, Cardin, Costa & Edwards, 1980). It seems that the uncoordinated pyridine does not have an important influence on the shortening of N(2)—Ru with respect to N(1)—Ru. This effect is present in both complexes, but it is more evident in the *cis*-*cis* compound [Ru—N(1) = 2.112 (2), Ru—N(2) = 2.049 (2) Å]. On the other hand the shorter Ru—N(2) distances with respect to the Ru—N(1) ones in both complexes are in agreement with the greater π acidity of the pyridazine ring. The C—O distances [1.126 (7), 1.132 (7) Å in (1) and 1.127 (4), 1.109 (4) Å in (2)] and the Ru—C—O angles [177.6 (5), 179.5 (5)° in (1) and 178.6 (3), 176.4 (3)° in (2)] are close to previously reported values (Clear, Kelly, O'Connell, Vos, Cardin, Costa & Edwards, 1980). The shortening of the C—O distance for the axial positions in the *cis*-*cis* compound with respect to the equatorial one in the *cis*-*trans* is noticeable.

Abstract. $[\text{Au}_2\text{Zn}(\text{C}_3\text{H}_5\text{O}_2)_8(\text{H}_2\text{O})_2]$, $M_r = 1079.9$, tetragonal, $I\bar{4}$, $a = 9.092$ (2), $c = 22.540$ (8) Å, $V = 1863.3$ Å³, $Z = 2$, $D_x = 1.925$ Mg m⁻³, $F(000) = 1040$, $\lambda(\text{Mo } \text{Ka}) = 0.71069$ Å, $\mu = 8.6$ mm⁻¹, $T = 293$ K. The structure was refined to $R = 0.030$ for 1631 unique observed reflections. The absolute structure was determined with an η refinement [$\eta = +1.06$ (3)]. A two-dimensional polymeric structure is observed; the Zn atom is coordinated octahedrally by four propionate oxygens and two *trans* waters, and the Au is coordinated by four propionate oxygens in a square plane. One propionate bridges Zn and Au, the other is only bonded to Au and has one non-coordinated O. The refinement of the wrong absolute structure led to a large

difference peak at 0, 0, 0.5, which could be successfully refined as an O atom. Incorrect absolute structure can thus lead to incorrect stoichiometry.

Introduction. In the course of our studies of gold(III) carboxylate complexes we have reported the structure of strontium digold(III) octaacetate dihydrate (Jones, 1984a). A detailed report of several other acetato-gold(III) complexes is in preparation. Here we show that the synthetic and structural principles can be extended to propionate complexes.

Experimental. Zinc digold(III) octahydroxide was prepared as a grey powder from aqueous solutions of $\text{NaAu}(\text{OH})_4$ and $\text{Zn}(\text{ClO}_4)_2$, and immediately dissolved in warm propionic acid. On standing for several days,
