# Structures of Trisodium Hexakis(formato)chromate(III) Tetrahydrate and Trisodium Hexakis(formato)molybdate(III) 

By Alan Hazell<br>Institute of Chemistry, Aarhus University, DK-8000 Århus C, Denmark

(Received 11 February 1988; accepted 5 April 1988)

#### Abstract

Na}_{3}\left[\mathrm{Cr}\left(\mathrm{CHO}_{2}\right)_{6}\right] .4 \mathrm{H}_{2} \mathrm{O}, M_{r}=463 \cdot 15\), triclinic, $\quad P \overline{1}, \quad a=6.463(1), \quad b=7.678$ (2), $\quad c=$ 8.741 (2) $\AA, \quad \alpha=101.46$ (1),$\quad \beta=97.26$ (1),$\quad \gamma=$ $78.74(1)^{\circ}, \quad V=415.2(2) \AA^{3}, \quad Z=1, \quad D_{x}=$ $1.852 \mathrm{Mg} \mathrm{m}^{-3}, \quad$ Mo $K a, \quad \lambda=0.71073 \AA, \quad \mu=$ $0.824 \mathrm{~mm}^{-1}, F(000)=235,298 \mathrm{~K}, R(F)=0.023$ for 2221 reflexions $[I>3 \sigma(I)]$ and 149 variables. $\mathrm{Na}_{3}\left[\mathrm{Mo}\left(\mathrm{CHO}_{2}\right)_{6}\right], M_{r}=435 \cdot 02$, orthorhombic, Pccn, $a=14.630$ (6), $\quad b=6.383$ (2), $c=13.888$ (5) $\AA, V=$ 1296.9 (8) $\AA^{3}, \quad Z=4, \quad D_{x}=2.228 \mathrm{Mg} \mathrm{m}^{-3}$, Mo $K \alpha$, $\lambda=0.71073 \AA, \quad \mu=1.143 \mathrm{~mm}^{-1}, \quad F(000)=852$, $293 \mathrm{~K}, R=0.026$ for 1524 reflexions $[I>3 \sigma(I)$ ] and 113 variables. In both complexes the metal atom is bonded to six formate ions, two with $M-\mathrm{O}-\mathrm{C}-\mathrm{O} t$ in the $s p$ and four in the $a p$ conformation. $\left[\mathrm{Cr}\left(\mathrm{CHO}_{2}\right)_{6}\right]^{3-}$ is centrosymmetric with $\mathrm{Cr}-\mathrm{O}$ distances of 1.973 (1), 1.979 (1) and 1.992 (1) $\AA$; the long $\mathrm{Cr}-\mathrm{O}$ bond is to an O atom which is hydrogen bonded to water. $\left[\mathrm{Mo}\left(\mathrm{CHO}_{2}\right)_{6}\right]^{3-}$ has twofold symmetry; the Mo--O distances are $2 \cdot 116$ (1), $2 \cdot 113$ (1) and $2 \cdot 110$ (1) $\AA$. In both cases, the coordination octahedra are distorted, the r.m.s. deviations of the angles from ideality being $2.4^{\circ}$ for $\mathrm{CrO}_{6}$ and $5.2^{\circ}$ for $\mathrm{MoO}_{6}$.

Introduction. Compounds of the type $\mathrm{Na}_{3}\left[\mathrm{M}^{\mathrm{II}}\left(\mathrm{CHO}_{2}\right)_{6}\right]$ seem only to be known for four metals, Fe (Weinland \& Reihlen, 1913), V (Barbieri, 1916), Cr (Stiasny \& Walther, 1928) and Mo (Brorson \& Schäffer, 1986). The structures of several formate

0108-2701/88/081362-04\$03.00
complexes of divalent metals are known which contain [ $M^{11}\left(\mathrm{CHO}_{2}\right)_{6}$ ] octahedra but in most of these (Weber, 1980, and references therein) the formates are bridges between the metal atoms. Formate groups can be bonded with $M-\mathrm{O}-\mathrm{C}-\mathrm{O} t$ ( $\mathrm{O} t=$ terminal O atom) in the $s p$ or $a p$ conformation, i.e. the torsion angle can be 0 or $180^{\circ}$, an extreme case of the former is when the formate is bidentate as in $\left[\mathrm{Mo}(\mathrm{CO})_{2}\left(\mathrm{PEt}_{3}\right)_{2}\left(\mathrm{CHO}_{2}\right)_{2}\right]$ (Brower, Winston, Tonker \& Templeton, 1986). The structures of the Cr and the Mo complexes are reported here.

Experimental. The chromium compound was synthesized by M. Brorson and C. Schäffer of Copenhagen University using Stiasny \& Walther's (1928) method and recrystallized by adding ethanol to an aqueous solution. A lath-shaped crystal, $0.45 \times 0.22 \times$ 0.18 mm , was mounted on a Picker FACS-1 diffractometer. Cell dimensions were determined from the setting angles of 25 reflections with $13 \leq \theta \leq 20^{\circ}$. Intensities were measured out to $[(\sin \theta) / \lambda]_{\max }=$ $0.7 \AA^{-1}$ using an $\omega-2 \theta$ scan and Nb -filtered Mo $K \alpha$ radiation, scan width $(2.0+0.692 \tan \theta)^{\circ}$, step length $0 \cdot 04^{\circ}, 1 \mathrm{~s}$ step $^{-1}$. Reflexions with $0 \leq h \leq 9,-10 \leq$ $k \leq 10,-12 \leq l \leq 12$ measured giving 2421 independent reflexions of which 2221 had $I>3 \sigma_{\text {cs }}(I)$. Reflexions 400 and 222 were monitored every 60 reflexions, the overall fall off in intensity was $3.7 \%$. No correction was made for absorption.

The structure was determined from Patterson and Fourier syntheses, H -atom positions were determined from a difference map. Least-squares refinement (on $F$ ), all non-H atoms refined anisotropically. Anomalousdispersion factors were included for Cr , no extinction correction was necessary. The weighting scheme was $w=1 / \sigma(F)^{2}$, where $\sigma(F)=\left[\sigma_{\mathrm{cs}}\left(F^{2}\right)+1 \cdot 02 F^{2}\right]^{1 / 2}-|F|$ and $\sigma_{\mathrm{cs}}\left(F^{2}\right)$ is the standard deviation of $F^{2}$ from counter statistics. Final $R=0.023, * w R=0.035, S=1.76$, $(\Delta / \sigma)_{\max }=0.02, \Delta \rho 0.29(3)$ to $-0.29(5) \mathrm{e} \AA^{-3}$. Frac-
*Lists of structure factors, anisotropic thermal parameters and some bond distances and angles for both compounds have been deposited with the British Library Document Supply Centre as Supplementary Publication No. SUP 44903 ( 18 pp .). Copies may be obtained through The Executive Secretary, International Union of Crystallography, 5 Abbey Square, Chester CH1 2HU, England.

tional coordinates are listed in Table 1, bond distances and angles in Table 3.
The molybdenum complex was synthesized by Brorson \& Schäffer (1986). A tabular crystal, $0.45 \times$ $0.40 \times 0.10 \mathrm{~mm}$, was mounted on a Huber diffractometer. Cell dimensions were determined from the setting angles of 30 reflexions, $8 \leq \theta \leq 16^{\circ}$. Intensities were measured out to $[(\sin \theta) / \lambda]_{\max }=0.7 \AA^{-1}$ using an $\omega-2 \theta$
scan and Nb -filtered Mo $K \alpha$ radiation, scan width $(1.2+0.692 \tan \theta)^{\circ}$ with 50 steps scan ${ }^{-1}$. A data set was first collected with $1 \mathrm{~s} \mathrm{step}{ }^{-1}$, reflexions with $l$ odd (to which Mo does not contribute) were remeasured with $2 \mathrm{~s} \mathrm{step}{ }^{-1}$. Reflexions with $0 \leq h \leq 20,0 \leq k \leq 8$, $-19 \leq l \leq 19$ were measured giving 1896 independent reflexions of which 1524 had $I>3 \sigma_{\mathrm{cs}}(I), R_{\text {int }}$ was 0.028 . Reflexions 400 and 006 were monitored every 50 reflexions, the overall fall off in intensity was $3 \cdot 0 \%$. The data were corrected for absorption, transmission factors ranged from 0.659 to 0.889 .

The structure was determined by the heavy-atom method, H -atom positions were located from a difference map. Least-squares refinement (on $F$ ), all non-H atoms refined anisotropically. Anomalous-dispersion factors were included for Mo, no extinction correction was necessary. The weighting scheme was $w=1 / \sigma(F)^{2}$ where $\sigma(F)=\left[\sigma_{c s}\left(F^{2}\right)+1.03 F^{2}\right]^{1 / 2}-|F|$ and $\sigma_{\mathrm{cs}}\left(F^{2}\right)$ is the standard deviation of $F^{2}$ from counter statistics. Final $R=0.026,{ }^{*} w R=0.040, S=1.28$, $(\Delta / \sigma)_{\max }=0.08, \Delta \rho 0.8(1)$ to $-1.5(1) \mathrm{e} \AA^{-3}$. Fractional coordinates are listed in Table 2, bond distances and angles in Table 3.

Computations were carried out on a VAX 11/780 computer with the following programs: INTEG based on the Nelmes (1975) algorithm for integration of intensities of the Cr complex, COLL5 based on the Lehmann \& Larsen (1974) algorithm for integrating the intensities of the Mo complex; DATAP and DSORT (State University of New York) for data processing; modified ORFLS (Busing, Martin \& Levy, 1962) for least-squares refinement; ORFFE (Busing, Martin \& Levy, 1964) for geometry; ORTEP (Johnson, 1965) for drawings. Scattering curves those of Cromer \& Mann (1968) for Mo, $\mathrm{Cr}, \mathrm{Na}, \mathrm{O}$, and C; those of Stewart, Davidson \& Simpson (1965) for H; anomalous-dispersion corrections for Cr and Mo from Cromer \& Liberman (1970).

Discussion. In the Cr complex (Fig. 1), the Cr atom which is situated on a symmetry centre is bonded to six unidentate formate ions. The six O atoms of the inner coordination sphere form a somewhat distorted octahedron $\dagger \quad\left(\Delta=2.4^{\circ}\right)$. The $\mathrm{Cr}-\mathrm{O}$ distances are 1.973 (1), 1.979 (1) and 1.992 (1) $\AA$. O(5) is hydrogen bonded to a water molecule, $\mathrm{O}(5) \cdots \mathrm{O}(7)$ is $2.937(1) \AA$ and the angle $\mathrm{O}(5) \cdots \mathrm{H}(71)-\mathrm{O}(7)$ is $175(2)^{\circ} . \mathrm{Cr}, \mathrm{O}(5), \mathrm{C}(3), \mathrm{O}(6), \mathrm{H}(71)$ and $\mathrm{O}(7)$ are nearly coplanar. The long $\mathrm{Cr}-\mathrm{O}$ bond is that to the

[^1]hydrogen-bonded $O(5)$ atom. The hydrogen-bonded formate has $\mathrm{Cr}-\mathrm{O}-\mathrm{C}-\mathrm{O} t$ in the $s p$ conformation. The complex anion is surrounded by 12 Na atoms which are in layers at $y \simeq 0.5 . \mathrm{Na}(1)$ which is on a symmetry centre is surrounded by a distorted octahedron ( $\Delta$ $=3.5^{\circ}$ ) of O atoms, $\mathrm{Na}(2)$ by seven O atoms which form a distorted pentagonal bipyramid ( $\Delta=7.2^{\circ}$ ). The $\mathrm{Na}-\mathrm{O}$ distances range from 2.334 (1) to 2.722 (1) $\AA$. The only O atom for which there is no short contact to Na is $\mathrm{O}(5)$ which is hydrogen bonded to a water molecule.

In the Mo complex (Fig. 2) the Mo atom is situated on a twofold axis and is bonded to six unidentate formate ions. The six O atoms of the inner coordination sphere form a somewhat distorted octahedron $\left(\Delta=5.2^{\circ}\right)$. The Mo-O distances are 2.116(1), $2 \cdot 113$ (1) and $2.110(1) \AA$, cf. 2.089 (1) $\AA$ in $\mathrm{Cs}\left[\mathrm{Mo}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]\left(\mathrm{SO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ (Brorson \& Gajhede, 1987). As in the Cr complex, two formate groups have $M-\mathrm{O}-\mathrm{C}-\mathrm{O} t$ in the $s p$ conformation; here also they are trans to each other although this is not required by symmetry unlike the centrosymmetric Cr complex. The anion and the $\mathrm{Na}^{+}$ions are in layers at $y \simeq 0.25$.

The bond lengths in the formate group are very similar for the two complexes, Table 4, and are much closer to those in the free acid than to those in the formate ion. Here the terminal $\mathrm{C}-\mathrm{O} t$ group is significantly shorter than that joined to the metal. Cotton and co-workers (Cotton, Darensbourg \& Kolthammer, 1981a,b; Cotton, Darensbourg, Kolthammer \& Kudarski, 1982) have shown that the geometry of carboxyl groups depends on the electrophilic character of the acceptor to which they are bonded: for good electrophiles $\mathrm{C}-\mathrm{O} t$ is short whereas for poor electrophiles, e.g. $\mathrm{Cr}(\mathrm{CO})^{5+}$, the two $\mathrm{C}-\mathrm{O}$ bonds are almost

Fig. 1. Stereoscopic drawing of $\left[\mathrm{Cr}\left(\mathrm{CHO}_{2}\right)_{6}\right]^{3-} .2 \mathrm{H}_{2} \mathrm{O}$.

Fig. 2. Stereoscopic drawing of $\left[\mathrm{Mo}\left(\mathrm{CHO}_{2}\right)_{6}\right]^{3-}$.

Table 4. Bond lengths ( $\AA$ ) in the two complexes compared with those in the free acid and in the formate ion

|  |  |  | Free | Formate <br> ion $^{c}$ |
| :--- | :---: | :---: | :---: | :---: |
|  | $\mathrm{Cr}^{a}$ | Mo $^{a}$ | acid $^{b}$ | $1.309(2)$ |
| $\mathrm{C}-\mathrm{O}-$ | $1.278(1)$ | $1.272(2)$ | $1.2561(4)$ |  |
| $\mathrm{C}-\mathrm{Ot}$ | $1.228(1)$ | $1.227(1)$ | $1.222(2)$ | $1.2561(4)$ |

identical. $\mathrm{C}-\mathrm{H}$ distances range from 0.93 (2) to 1.09 (2) $\AA$ in the Cr complex and from 1.01 (4) to 1.02 (4) $\AA$ in the Mo complex.

In the hexaformato complexes, the $M-\mathrm{O}-\mathrm{C}-\mathrm{O}$ geometry can be characterized by (a) the planarity of $M-\mathrm{O}-\mathrm{C}-\mathrm{O} t$, $(b)$ its rotation about the $M-\mathrm{O}$ bond, (c) an in-plane deformation of the $M-\mathrm{O}-\mathrm{C}$ angle and (d) whether $M-\mathrm{O}-\mathrm{C}-\mathrm{O} t$ is $s p$ or $a p$. The $M-\mathrm{O}-\mathrm{C}-\mathrm{O}$ torsion angles are close to zero or $180^{\circ}$, i.e. the atoms are almost coplanar. The torsion angles $\tau=\mathrm{C}-\mathrm{O}-$ $M-\mathrm{O}$ might be expected to be 0 or $180^{\circ}$, i.e. the formate group to lie close to an $\mathrm{O}-M-\mathrm{O}$ plane or to be about $45^{\circ}$, i.e. the plane of the formate group bisecting two $\mathrm{O}-M-\mathrm{O}$ planes. For the Cr complex, all formates are 'bisecting', for the Mo complex two are 'bisecting' and four are 'in-plane'. In $\mathrm{Sr}\left[\mathrm{Cu}\left(\mathrm{CHO}_{2}\right)_{6}\right] .8 \mathrm{H}_{2} \mathrm{O}$ (Baggio, de Perazzo \& Polla, 1985) four are 'bisecting'. The in-plane deformation is greatest for the $s p$ formate groups with $M-\mathrm{O}-\mathrm{C}$ being $5-10^{\circ}$ larger than for the ap formates.

I am indebted to Claus Schäffer and Michael Brorson for providing the crystals and to the Carlsberg Foundation for the Huber diffractometer.

    $\dagger$ The deviation, $\Delta$, of a polyhedron $M X_{n}$ from the ideal polyhedron $M Y_{n}$ is measured by considering the angles $\delta \theta$ between $M X_{i}$ and $M Y_{i}$ and rotating $M Y_{n}$ so that $n \Delta^{2}=\Sigma(\delta \theta)^{2}$ is a minimum. The centres of the two polyhedra are assumed to coincide. This one-parameter measure of the deviation is closely related to that proposed by Dollase (1974), i.e. the r.m.s. distance between the vertices of the observed and ideal polyhedra.
