

Structure of (Dimethylphenylphosphine)oxotris(trimethylsilylmethyl)rhenium(V)

BY DAVID M. HOFFMAN,* DIMITRIOS LAPPAS AND DERK A. WIERDA

Department of Chemistry, Harvard University, 12 Oxford Street, Cambridge, MA 02138, USA

(Received 12 January 1988; accepted 25 April 1988)

Abstract. [ReO₂{P(CH₃)₂(C₆H₅)}{Si(CH₂)(CH₃)₃}]₃, $M_r = 602.08$, triclinic, $P\bar{1}$, $a = 11.402$ (2), $b = 16.306$ (3), $c = 16.443$ (3) Å, $\alpha = 69.03$ (1), $\beta = 80.87$ (2), $\gamma = 89.62$ (2)°, $V = 2814.0$ Å³, $Z = 4$, $D_x = 1.42$ g cm⁻³, $\lambda(\text{Mo } K\alpha) = 0.71073$ Å, $\mu = 45.65$ cm⁻¹, $F(000) = 1215.8$, $T = 192$ (1) K, final $R = 0.0540$ for 3567 unique reflections with $F_o > 6\sigma(F_o)$ and 385 variables. The crystals have two independent molecules in the asymmetric unit. The coordination geometry about the Re atom in both molecules is approximately square pyramidal. In each case the oxo ligand occupies the apical site and the basal plane is occupied by a phosphine ligand and three alkyl ligands. Selected bond distances and angles: molecule A: $d(\text{Re}-\text{O}) = 1.659$ (13), $d(\text{Re}-\text{C}) = 2.128$ (20) av., $d(\text{Re}-\text{P}) = 2.415$ (6) Å, $\text{O}-\text{Re}-\text{C} = 109.7$ (8) av., $\text{O}-\text{Re}-\text{P} = 107.0$ (5)°; molecule B: $d(\text{Re}-\text{O}) = 1.666$ (13), $d(\text{Re}-\text{C}) = 2.128$ (22) av., $d(\text{Re}-\text{P}) = 2.430$ (5) Å, $\text{O}-\text{Re}-\text{C} = 111.4$ (7) av., $\text{O}-\text{Re}-\text{P} = 108.7$ (6)°.

Experimental. (Dimethylphenylphosphine)oxotris(trimethylsilylmethyl)rhenium(V) was prepared according to the literature method (Cai, Hoffman, Lappas, Woo & Huffman, 1987). Purple crystals were grown from a cold acetonitrile solution (253 K).

A crystal with dimensions 0.21 × 0.15 × 0.13 mm was mounted under nitrogen on a glass fiber. Lattice parameters were determined by a least-squares fitting of 50 reflections (15 < 2θ < 30°). Nicolet R3m/V diffractometer equipped with an LT-1 low-temperature device, graphite-monochromated Mo $K\alpha$ radiation; $\theta/2\theta$ scan mode, scan width (1.2 + dispersion)°; 3.5 < 2θ < 45°; 7402 reflections measured, 3835 unique ($R_{\text{int}} = 0.027$), 3567 observed [$F_o > 6\sigma(F_o)$]. Index range: -12 ≤ h ≤ 12, -17 ≤ k ≤ 17, 0 ≤ l ≤ 17. Three intensity control reflections were monitored every 60 reflections of data collection; no crystal decay observed. Lorentz-polarization correction and empirical absorption correction (ψ scans): transmission 0.983–0.866. No extinction correction was applied. The structure was solved from Patterson and difference syntheses.

Non-H atoms refined anisotropically by full-matrix least-squares methods with the exception of the two

phenyl rings, which were refined as rigid groups. H atoms were placed in idealized positions [C—H = 0.96 Å, $U(\text{H}) = 1.2 U_{\text{eq}}(\text{C})$]. The function $w(\Delta F)^2$ was minimized { $w = 1/[\sigma^2(F) + 0.0036F^2]$ }. Final $R =$
