Discussion. The Fe atom occupies a special position (2a) of space group Imm2, thus the $\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]^{4-}$ unit has $m m 2$ symmetry. The Li ions also lie in special positions, $(4 c)$ and ( $4 d$ ), and one of the oxygen atoms, $\mathrm{O}(2)$, of the coordination water molecules also occupies a special position (2b); therefore the hydrated cation $\left[\mathrm{Li}_{4}\left(\mathrm{OH}_{2}\right)_{5}\right]^{4+}$ also possesses $m m 2$ symmetry. However, the HMT molecule only shows $m$ symmetry; the atoms $\mathrm{C}(13), \mathrm{C}(14) \mathrm{N}(12)$ and $\mathrm{N}(13)$ lie in special positions (4c).

Both compounds $\mathrm{Li}_{n}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right] \cdot 2 \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{~N}_{4} \cdot 5 \mathrm{H}_{2} \mathrm{O}$ (n $=3,4$ ) may be regarded as a body-centred $\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]^{n-}$ packing containing HMT molecules in tetrahedral interstices and $\left[\mathrm{Li}_{n}\left(\mathrm{OH}_{2}\right)_{s}\right]^{n+}$ ions in octahedral interstices.

The two compounds can be distinguished by structure analysis, by IR $v(\mathrm{C} \equiv \mathrm{N})$ stretching frequencies (2115, $2014 \mathrm{~cm}^{-1}$ for $\mathrm{Fe}^{3+}, \mathrm{Fe}^{2+}$ respectively) and by their Mössbauer spectra: the $\mathrm{Fe}^{2+}$ compound gives an undistorted singlet whereas the $\mathrm{Fe}^{3+}$ compound, which contains disordered Li ions, gives two doublets.

The structure is stabilized by hydrogen bonds between water molecules and N atoms $\mathrm{N}(11), \mathrm{N}(13)$ and $\mathrm{N}(1)$, which are not coordinated to Li atoms. The mean $\mathrm{O}-\mathrm{H} \cdots \mathrm{N}$ distance is $2.90 \AA$.

The authors thank Professor E. Riedel and Dr J. Kähler for performing the Mössbauer study. Financial support by the Deutsche Forschungsgemeinschaft and the Fonds der Chemischen Industrie is gratefully acknowledged.

# Diiodobis(triphenylphosphine)nickel(II) 

By Roger W. Humphry and Alan J. Welch<br>Department of Chemistry, University of Edinburgh, Edinburgh EH9 3JJ, Scotland<br>and Dorothy A. Welch<br>Department of Computer Science, University of Edinburgh, Edinburgh EH9 3JZ, Scotland

(Received 9 May 1988; accepted 8 June 1988)

Abstract. $\left[\mathrm{NiI}_{2}\left(\mathrm{C}_{18} \mathrm{H}_{15} \mathrm{P}\right)_{2}\right], M_{r}=837 \cdot 09$, monoclinic, $P 2_{1} / c, \quad a=19.361(17), \quad b=10.220(5), \quad c=$ 17.995 (13) $\AA, \quad \beta=112.26(7)^{\circ}, \quad V=3296$ (3) $\AA^{3}, \quad Z$ $=4, D_{x}=1.687 \mathrm{Mg} \mathrm{m}^{-3}$, Mo $K \alpha, \lambda=0.71069 \AA, \mu$ $=2.56 \mathrm{~mm}^{-1}, F(000)=1640, T=291 \mathrm{~K}, R=0.0780$ for 4302 independent observed reflections. The nickel atom has a distorted tetrahedral geometry, angles subtended at the metal ranging from $103 \cdot 40$ (9) to $118.12(6)^{\circ}$. Average $\mathrm{Ni}-\mathrm{I}$ and $\mathrm{Ni}-\mathrm{P}$ distances are 2.5307 (25) and 2.382 (4) $\AA$, respectively.

Introduction. Dihalogenobisphosphine complexes of the nickel triad are exceptionally well known species, frequently being cited as classic examples of tetrahedral ( Ni ) or square-planar ( $\mathrm{Ni}, \mathrm{Pd}, \mathrm{Pt}$ ) transitionmetal complexes (and, for certain of the nickel species, examples of facile interconversion between structural isomers).

0108-2701/88/101717-03\$03.00

One of our ongoing interests is the application of molecular-orbital (MO) methods in transition-metal chemistry, one aspect of which concerns the reproducibility of results derived from MO calculations performed at differing levels of sophistication. We considered that the series of molecules $X_{2} \mathrm{Ni}\left(\mathrm{P}_{3}\right)_{2}$ would represent suitable species for comparative MO calculations, since they are relatively simple, have variable geometries, and contain both $\pi$-donor and $\pi$-acceptor ligands. However, we were very surprised to discover that no precise structural data (the starting point for these calculations) on any iodide was available in the literature. Accordingly, we herein present the derived molecular parameters of $\mathrm{I}_{2} \mathrm{Ni}\left(\mathrm{PPh}_{3}\right)_{2}$.

Experimental. Compound prepared according to the literature (Venanzi, 1958), and purity checked by microanalysis; relatively poor quality black plates

Discussion. The unit-cell dimensions previously reported for this compound [Garton, Henn, Powell \& Venanzi (GHPV) (1963)] have been confirmed, but the correct space group is $P 2_{1} / c$ and not either $P c$ or $P 2 / c$. Table $1^{*}$ lists the coordinates of refined atoms and equivalent isotropic thermal parameters, whilst Table 2 details the internuclear distances and interbond angles determined. A perspective view of a single molecule is shown in Fig. 1.

The compound crystallizes with no important contacts between adjacent molecules. The geometry at nickel is clearly distorted tetrahedral, angles varying from $103.40(9)[\mathrm{I}(1)-\mathrm{Ni}-\mathrm{P}(1)]$ to $118.12(6)^{\circ}$ [ $\mathrm{I}-$ $\mathrm{Ni}-\mathrm{I}]$. The $\mathrm{P}-\mathrm{Ni}-\mathrm{P}$ angle is $105 \cdot 30(11)^{\circ}$. This continues a smooth decrease from $116.6^{\circ}$ in $\mathrm{Cl}_{2}-$ $\mathrm{Ni}\left(\mathrm{PPh}_{3}\right)_{2}$ (GHPV, 1963), and $110.4(2)^{\circ}$ in $\mathrm{Br}_{2}-$ $\mathrm{Ni}\left(\mathrm{PPh}_{3}\right)_{2}$ (Jarvis, Mais \& Owston, 1968). However, it is not the case that as $\mathrm{P}-\mathrm{Ni}-\mathrm{P}$ decreases, $X-\mathrm{Ni}-X$ increases along the same series. In the dichloride the

[^0]

Fig. 1. Perspective view of $\mathrm{I}_{2} \mathrm{Ni}\left(\mathrm{PPh}_{3}\right)_{2}$ ( $50 \%$ thermal ellipsoids). The numbering of C atoms in the phenyl rings is cyclic, $\mathrm{C}(i j k)$, where $i$ is the number of the attached phosphorus, $j=1-3$, and $k=1-6$. H atoms, which have been given an artificial radius of $0.1 \AA$ for clarity, carry the same number as the C atom to which they are attached.
latter angle is $123.3^{\circ}$, in the dibromide $126.3(1)^{\circ}$, and in the diiodide herein, only $118.12(6)^{\circ}$. In fact, in terms of the root-mean-square distortion (r.m.s.d.) of the angles at nickel from the tetrahedral ideal, the diiodide (r.m.s.d. $4.99^{\circ}$ ) is the least distorted molecule, the dichloride intermediate (r.m.s.d. $7.56^{\circ}$ ), and the dibromide the most distorted (r.m.s.d. $8 \cdot 10^{\circ}$ ). These results emphasize the dangers of the assumption of simple structural patterns in a series of seemingly innocuous analogues. Since none of the three compounds are pairwise isomorphous it is certainly possible that differing intramolecular steric requirements of the triphenylphosphine ligands are at least partially responsible for the observed angles at nickel, but we have not pursued this possibility in any detail.

The $\mathrm{Ni}-\mathrm{I}$ distances in $\mathrm{I}_{2} \mathrm{Ni}\left(\mathrm{PPh}_{3}\right)_{2}$ are barely different, average $2.5307(25) \AA$. In contrast, $\mathrm{Ni}-\mathrm{P}(2)$ is longer than $\mathrm{Ni}-\mathrm{P}(1)$ by 0.081 (4) $\AA$, the average $\mathrm{Ni}-\mathrm{P}$ distance being 2.382 (4) $\AA$. This is longer than that observed in the dichloride ( $2.28 \AA$ ) and the dibromide ( $2.333 \AA$ ), a trend that can readily be correlated with the decreasing $\pi$-donor capability of the heavier halides. On the other hand, the changes in the average $\mathrm{Ni}-X$ distance [dichloride to dibromide, $0.07 \AA$ (less than the difference in covalent radii), and dibromide to diiodide, $0.19 \AA$ (exactly the difference in covalent radii)] do not easily fit with this pattern. A case could be made for a redetermination of $\mathrm{Cl}_{2} \mathrm{Ni}\left(\mathrm{PPh}_{3}\right)_{2}$, for which only a rather inaccurate two-dimensional study is currently available (GHPV, 1963).
