The six-membered chelate rings have slightly different conformations. While the ligand involved in the $\mathrm{Cu}-\mathrm{N}$ bridge is planar within 0.028 (4) $\AA$, the ring involved in plane-to-plane coupling adopts a half-chair conformation with a dihedral angle along the $0 \cdots \mathrm{O}$ vector of $171.6(3)^{\circ} ; \mathrm{Cu}$ is displaced from the ligand planes by 0.067 (1) and 0.228 (1) $\AA$ respectively. A half-chair conformation is also observed in the Cu (CNpaac) $)_{2}$ complex with a $0.5 \AA$ metal displacement and a $158.3^{\circ}$ angle of fold. The average chelate 'bite' distance is 2.768 (3) $\AA$. Bond lengths and angles in the ligands are normal (see Table 3). We note that the $\mathrm{C}-\mathrm{CN}$ bonds [av. 1-436(4) $\AA$ ] are longer than the in-ring $\mathrm{C}-\mathrm{C}$ bonds [av. 1.416 (4) $\AA$ ].

The intrinsic $\mathrm{mmm}\left(D_{2 h}\right)$ point symmetry of the $\mathrm{Cu}(\mathrm{CNacac})_{2}$ molecule is entirely lost in the crystal as only one of the CN groups is involved in an intermolecular coordination. The $\mathrm{C}\left(4^{\prime}\right)-\mathrm{N}\left(7^{\prime}\right) \cdots \mathrm{Cu}^{\prime \prime \prime}$ angle is $115.7(2)^{\circ}$ compared to $149.8(9)^{\circ}$ in $\mathrm{Cu}(\mathrm{CNpaac})_{2}$. The N atom of the second cyano group is distant from Cu ; its closest intermolecular contact is $\mathrm{N}(7) \cdots \mathrm{C}\left(3^{\prime \prime i}\right) 3.493(5) \AA$.

The authors are indebted to Dr F. H. Allen for affording one of us (JM) an opportunity to access the

Cambridge Structural Database during the XIVth IUCr Congress in Perth, Australia.

# Structure of Dicopper Tetramethylammonium Pentachloride 

By W. G. Haije, J. A. L. Dobbelaar and W. J. A. Maaskant<br>Gorlaeus Laboratories, Leiden University, PO Box 9502, 2300 RA Leiden, The Netherlands

(Received 6 June 1988; accepted 7 November 1988)

Abstract. $\mathrm{Cu}_{2}\left[\mathrm{~N}\left(\mathrm{CH}_{3}\right)_{4}\right] \mathrm{Cl}_{5}, M_{r}=378.56$, monoclinic, $P 2_{1} / c, \quad a=6.073(1), \quad b=19.58$ (1),$c=10.62$ (1) $\AA$, $\beta=99.46(5)^{\circ}, \quad V=1245 \cdot 1$ (4) $\AA^{3}, \quad Z=4, \quad D_{x}=$ $2.02 \mathrm{~g} \mathrm{~cm}^{-3}$, Мо $K \alpha, \lambda=0.71073 \AA, \mu=44.67 \mathrm{~cm}^{-1}$, $F(000)=744, \quad T=293 \mathrm{~K}, \quad \omega R=0.0329$ for 3450 reflections. The building block of this compound consists of a linear array of four edge-sharing square pyramids (approximate $C_{4 v}$ symmetry) with each alternate pyramid upside down. These building blocks are edge-sharing via the apical $\mathrm{Cl}^{-}$ions so as to form sheets. The sheets are held together by the large tetramethylammonium (TMA) ions.

Introduction. The research by our group is focused in part on the structural and magnetic properties of ternary halides in the system $A X-B X_{2}$ in which $A=\mathrm{Rb}^{+}, \mathrm{Cs}^{+}$or $\left(\mathrm{CH}_{3}\right)_{4} \mathrm{~N}^{+}, B=\mathrm{Cu}^{2+}$ and $X=\mathrm{Cl}^{-}$. The most thoroughly investigated structure class in this

[^0]system is the hexagonal perovskite $A B X_{3}$ (2L). The cooperative Jahn-Teller effects in the $\mathrm{Cu}^{2+}$ and $\mathrm{Cr}^{2+}$ compounds were the main field of interest (Crama \& Maaskant, 1983; Maaskant \& Haije, 1986).

We previously reported (Haije, Dobbelaar \& Maaskant, 1986) the crystal structure of a new compound in the same ternary system: $\mathrm{TMPCu}_{2} \mathrm{Cl}_{5}$ (TMP $=$ tetramethylphosphonium). This compound has a similar composition to $\mathrm{TMACu}_{2} \mathrm{Cl}_{5} \quad$ (TMA $=$ tetramethylammonium) which was first synthesized by Weenk (1976) who only determined the lattice parameters. The present investigation was undertaken to prove the similarity between the two compounds, which, however, does not appear to exist after all.

Experimental. Single crystals were grown from an aqueous solution, acidified with concentrated hydrochloric acid, containing TMACl and $\mathrm{CuCl}_{2}$ in the ratio

1:2. The solution yielded three types of crystal, reddish brown ( $\mathrm{TMACuCl}_{3}$ ), yellow ( $\mathrm{TMA}_{2} \mathrm{CuCl}_{4}$ ) and dark green, which were separated by hand. The green modification appeared to have the same unit-cell dimensions as given by Weenk (1976) for the TMA$\mathrm{Cu}_{2} \mathrm{Cl}_{5}$ compound.

Dark-green oblique crystals, $0.6 \times 0.4 \times 0.4 \mathrm{~mm}$, Enraf-Nonius four-circle diffractometer, graphitemonochromated Mo $K \alpha$ radiation, 24 reflections ( $-16.47<\theta<16.45^{\circ}$ ) used for determination of unit-cell dimensions, from systematic absences $h 0 l$ $l=2 n, 0 k 0 k=2 n$ it was concluded that the space group is $P 2_{1} / c .5824$ reflections were measured ( $2<$ $\theta<35^{\circ}$ ), of which 5608 were independent, $R_{\text {int }}=$ $0.0324,3456$ observed and 2152 non-significant [for observed reflections: $I>2 \sigma(I)$ ], $h 0$ to $9, k 0$ to 31 , $l-17$ to 16 , three standard reflections ( $3 \overline{6} \overline{3}, 206$, $00 \overline{8})$, decay scattering power $8.97 \%$, observed reflections were corrected for this variation; e.s.d. of standard reflections $1.9 \%$. Lp correction, absorption correction (de Graaff, 1973), min. and max. transmission 0.373 and 0.562 respectively, scattering factors from International Tables for X-ray Crystallography (1974) with correction for real and imaginary parts of anomalous dispersion. Function minimized during the least-squares refinement $\sum w\left(\left|F_{\text {obs }}\right|-\left|F_{\text {calc }}\right|\right)^{2}, \quad w=$ $1 / \sigma(F)^{2}, \sigma(F)$ e.s.d. calculated from counting statistics
and by taking into account the above-mentioned corrections. For all calculations, computer programs were written or modified by Rutten-Keulemans and de Graaff and used on the Leiden University IBM 3081 computer. The determination of the crystal structure was started by solving a Patterson map for the heavy atoms. Subsequent Fourier syntheses were used to find all non- H atoms. Refinement of all $\mathrm{Cu}, \mathrm{Cl}, \dot{\mathrm{C}}$ and N positions and anisotropic thermal parameters resulted in $w R=5.97 \%$. Including the H atoms on calculated positions lowered $w R$ to $3.74 \%$. The calculated moduli of some of the strongest reflections were still much larger than the observed values, making correction for extinction (Zachariasen, 1969) necessary; final $w R$ is $3 \cdot 29 \%(R=2 \cdot 8 \%, S=1 \cdot 2)$. The ratio of the maximum least-squares shift to e.s.d. is smaller than 0.07 (isotropic $B$ of H atom). The maximum and minimum heights in the final difference Fourier synthesis are 0.46 and $0.28 \mathrm{e}^{-3}$ respectively (statistical height: $0.20 \mathrm{e}^{-3}$ ).

Discussion. The positional parameters are given in Table 1.* Relevant bond lengths and angles are also tabulated (Table 2). The structure of this compound is clearly different from that found for the phosphonium analog discussed in the Introduction (Haije, Dobbelaar \& Maaskant, 1986), which explains the difference in colour. The TMP compound is red

Square, Chester CH1 2HU, England.

Fig. 1. Perspective view of the $\mathrm{Cu}-\mathrm{Cl}$ network. The ac plane is parallel to the plane of the paper; the $b$ axis is pointing out of this plane. The four-pyramid building block is easily recognized, as are the two distinct copper species (five- and six-coordinated). For clarity, the $\mathrm{CH}_{3}$ groups of the TMA ions are left out of the drawing ( N : non-bonded open ellipsoid).
whereas the TMA compound is green. In the TMA case the structure contains two definitely different Cu sites, one $[\mathrm{Cu}(2)$; coordinated to $\mathrm{Cl}(1), \mathrm{Cl}(2), \mathrm{Cl}(3), \mathrm{Cl}(4)$ and $\mathrm{Cl}(5)$ ] being square pyramidal (five coordinated) and the other $[\mathrm{Cu}(1)$; coordinated to $\mathrm{Cl}(1), \mathrm{Cl}(2)$, two $\mathrm{Cl}(4)$ ions and two $\mathrm{Cl}(5)$ ions] effectively six coordinated although the site symmetry remains approximately $C_{4 v}$ as one of the apical Cl ions $[\mathrm{Cl}(4)]$ has a much larger bond length [ 3.2446 (7) $\AA$ ]. The squarepyramidal environment of Cu is distorted via a pseudo-Jahn-Teller effect in the ground state of the $C_{4 v}$ complex as described for other compounds by Bacci (1979).

The $\mathrm{Cu}-\mathrm{Cl}$ backbone consists of linear arrays of four edge-sharing pyramids coupled together so as to form sheets (Fig. 1) which are held together by the TMA ions.

From a magnetochemists' point of view it might be interesting to see whether this system behaves mag-
netically as weakly coupled linear tetramers of four coupled $S=\frac{1}{2}$ ions, since the unpaired electron is most likely confined to the $d_{x^{2}-y^{2}}$ orbital which is in the equatorial plane of the pyramid (the $d_{z^{2}}$ orbital is pointing toward the apical Cl ions).

dichlorotris(triphenylphosphine)ruthenium and $1,1,1,-$ 5,5,5-hexafluoro-2,4-pentanedione in cold (I) and warm (II) benzene under aerobic conditions. The Ru atoms in both compounds are in octahedral coordination with two O atoms of the bidentate ligand, the P atoms of two $\mathrm{PPh}_{3}$ groups and two Cl atoms. In (I), the Cl atoms are trans and the $\mathrm{PPh}_{3}$ groups are cis, while in (II) these conformations are reversed.

Introduction. The ruthenium(II) and osmium(II) complexes $\left[\mathrm{MCl}_{2}\left(\mathrm{PPh}_{3}\right)_{3}\right]$ undergo 'oxidative substitution' reactions with $\beta$-diketones in benzene solution under aerobic conditions to form the corresponding $\beta$-diketonates $\left[M \mathrm{Cl}_{2}\left\{R \mathrm{C}(\mathrm{O}) \mathrm{CHC}(\mathrm{O}) R^{\prime}\right\}\left(\mathrm{PPh}_{3}\right)_{2}\right] \quad\left(R, R^{\prime}=\right.$ $\mathrm{CH}_{3}, \mathrm{CF}_{3}, \mathrm{C}_{2} \mathrm{H}_{5}$ or $\left.\mathrm{C}_{6} \mathrm{H}_{5}\right)$ one of which, $\left[\mathrm{RuCl}_{2}-\right.$ (c) 1989 International Union of Crystallography
