Abstract. $\mathrm{C}_{13} \mathrm{H}_{23} \mathrm{NO}_{9}, M_{r}=337.33$, orthorhombic, $P 2_{12} 2_{1} 2_{1}, \quad a=8.8479$ (9),$\quad b=9.691$ (2),$\quad c=$ $18 \cdot 121(4) \AA, \quad V=1553.8(5) \AA^{3}, \quad Z=4, \quad D_{x}=$ $1.442 \mathrm{Mg} \mathrm{m}^{-3}, \quad \lambda($ Мо $K \alpha)=0.71073 \AA, \quad \mu($ Мо $K \alpha)$ $=0.11 \mathrm{~mm}^{-1}, F(000)=720, T=100 \mathrm{~K}$, final $R=$ 0.034 for 3398 observed diffractometer data. The conformation of the glycerol side chain is the same as in the structures of the two $\beta$ forms of $N$ acetylneuraminic acid. The crystal consists of a twodimensional network of hydrogen-bonded molecules and in the third direction there are only hydrophobic contacts.

Introduction. Sialic acids frequently occur as $\alpha$-glycosidically linked terminal groups of carbohydrate chains in glycoproteins and glycolipids (Corfield \& Schauer, 1982). The large range of their biological activity includes, for example, (anti)recognition of low- and high-molecular-weight compounds, influ-

0108-2701/90/030407-04\$03.00
ence on transport processes, hormone action, cellular adhesiveness and the life span of glycoproteins (Reuther, Köttgen, Bauer \& Gerok, 1982). For these biological functions the charge and the conformation of the molecules are essential features.
$N$-Acetylneuraminic acid is one of the most frequently occurring sialic acids. So far only the crystal structures of two $\beta$-glycosidical forms, $\beta$-D-NacetyIneuraminic acid dihydrate ( $\beta \mathrm{Neu} 5 \mathrm{Ac}$; Flippen, 1973) and $\beta$-D- $N$-acetylneuraminic acid methyl ester monohydrate ( $1 \mathrm{Me} \beta$ Neu5Ac; O'Connell, 1973) have been determined. It is of interest to study the $\alpha$-glycosidic form of neuraminic acid because it is this form that occurs in nature, and effects on the conformation with respect to the $\beta$ forms can be expected by the axial position of the carboxyl group. Therefore, we here report the crystal and molecular structure of $\alpha$-D- N -acetyl-1- O -methylneuraminic acid methyl ester ( $1,2 \mathrm{diMe} \alpha \mathrm{Neu} 5 \mathrm{Ac}$ ). Because the intra-

[^0]and intermolecular hydrogen-bonding scheme is of major interest the experiment has been performed at low temperature in order to locate H atoms.

Experimental. Colourless transparent block-shaped crystals ( $0.18 \times 0.10 \times 0.10 \mathrm{~mm}$ ), obtained by vapour diffusion of a solution in methanol against diethyl ether. Enraf-Nonius CAD-4 diffractometer, temperature 100 K , Mo $K \alpha$ radiation, graphite monochromator, lattice dimensions determined using 22 reflections in $\theta$ range 21 to $23^{\circ}$; the space group was established by observed systematic absences $h 00$ with $h=2 n+1,0 k 0$ with $k=2 n+1$ and $00 l$ with $l=2 n+$ 1. $\omega / 2 \theta$ scan mode, scan width $(0.75+0.35 \tan \theta)^{\circ}$, $2 \theta_{\text {max }}=56^{\circ}, h=-11$ to $11, k=0$ to $12, l=-23$ to 23; 7926 reflections measured, $R_{\text {int }}=0.03$ from merging 3750 equivalent pairs; 3398 above $2 \cdot 5 \sigma(I)$ level. Three periodically measured standard reflections $(10 \overline{6}, 106, \overline{1} 23)$ showed no significant decay in intensity during data collection, only slight absorption noticed ( $<10 \%$ in $\psi$ scan) and not corrected for, Lp correction. Structure solved by direct methods (SHELXS84; Sheldrick, 1984). Refinement on $F$ by full-matrix least squares (SHELX76; Sheldrick, 1976) with anisotropic temperature factors for all non-H atoms. All H atoms could be located from a threedimensional difference Fourier map; their positions and one common thermal parameter were subsequently refined. Scattering factors were taken from Cromer \& Mann (1968), anomalous-dispersion corrections from Cromer \& Liberman (1970). Convergence at $R=0.034, w R=0.030$ where $w=1 / \sigma^{2}\left(F_{o}\right)$. Max. and min. densities in final difference synthesis were 0.46 and $-0.33 \mathrm{e} \AA^{-3}$ respectively. $\Delta / \sigma=0.004$ (av.) and 0.052 (max.)

Discussion. The final atomic positional and isotropic thermal parameters are given in Table 1.* The molecular conformation and atomic numbering is shown in Fig. 1. Bond distances, bond angles and relevant torsion angles for non-H atoms are listed in Table 2. The geometric calculations were performed with the EUCLID package (Spek, 1982). Bond distances and angles are similar to those found in other saccharides (Arnott \& Scott, 1972) although some peculiarity occurs in the anomeric region. Arnott \& Scott (1972) and Jeffrey, Pople, Binkley \& Vishveshwara (1978) have studied the changes in geometry near the anomeric centre for the various anomers, by crystal-structure statistics and by theoretical methods. In line with their observations, the

anomeric $\mathrm{C}-\mathrm{O}$ bond length ( $1.403 \AA$ ) is shortened with respect to the average single $\mathrm{C}-\mathrm{O}$ bond length in the title compound ( $1 \cdot 429 \AA$ ). These authors also found that the difference in the two ring $\mathrm{C}-\mathrm{O}$ bond lengths appears to be characteristic for the specific anomer, i.e. the bond involving the anomeric C atom is shorter when the anomeric $\mathrm{C}-\mathrm{O}$ bond is in the axial position. In normal D-hexopyranoses this corresponds to the $\alpha$ anomer, but because $\mathrm{C}(8)$ is the reference atom for the D configuration in Neu5Ac, and $\mathrm{C}(6)$ has the l-glycero configuration, the axial position of the anomeric $\mathrm{C}-\mathrm{O}$ bond corresponds to the $\beta$ anomer. Thus one would expect the $\mathrm{C}(2)-\mathrm{O}(6)$ and $\mathrm{C}(6)-\mathrm{O}(6)$ bonds to be nearly equal in $1,2 \mathrm{diMe} \alpha \mathrm{Neu} 5 \mathrm{Ac}$ but $\mathrm{C}(2)-\mathrm{O}(6)$ appears to be shorter by $0.02 \AA$. Moreover, for $\beta$-d-hexoses, the $\mathrm{O}-\mathrm{C}-\mathrm{O}$ angle at the anomeric C atom appears to be narrow (average $107.3^{\circ}$ ) and the ring $\mathrm{C}-\mathrm{O}-\mathrm{C}$ angle appears to be $111.6^{\circ}$ on the average (Arnott \& Scott, 1972). The value of $107 \cdot 1^{\circ}$ for $\mathrm{O}(2)-\mathrm{C}(2)-$ $\mathrm{O}(6)$ in $1,2 \mathrm{diMe} \alpha \mathrm{Neu} 5 \mathrm{Ac}$ is in good agreement with the above, but the value of $114.4^{\circ}$ for $\mathrm{C}(2)-\mathrm{O}(6)$ $C(6)$ is unusually large and close to what is common for $\alpha$-hexoses. Thus it seems that the geometrical features in the anomeric region are not so characteristic for the specific anomer when a carboxyl group is attached to the anomeric C atom.

The ring has the normal ${ }^{2} C_{5}$ shape, somewhat distorted toward a ${ }^{6} H_{5}$ half-chair conformation with puckering parameters $Q=0.577$ (2) $\AA, \theta=162.2$ (2) and $\varphi=92.2$ (2) (Cremer \& Pople, 1975). Comparison with the puckering parameters for $1 \mathrm{Me} \beta \mathrm{Neu} 5 \mathrm{Ac}$ ( $Q=0.540 \AA, \theta=176 \cdot 0, \varphi=212 \cdot 9^{\circ}$ ) and $\beta \mathrm{Neu} 5 \mathrm{Ac}$ ( $Q=0.567 \AA, \theta=177.3, \varphi=89.0^{\circ}$ ) shows that due to the axial position of the carboxyl group the ring in the $\alpha$ form is more distorted.
It is of interest to compare the conformations of the carboxyl group, the $N$-acetyl group and the glycerol side chain for the three $N$-acetylneuraminic acids. The relevant torsion angles can be found in Table 2. The $\mathrm{C}=\mathrm{O}$ bond of the carboxyl group is approximately coplanar with the ring $\mathrm{C}-\mathrm{O}$ bond in $1,2 \mathrm{diMe} \alpha \mathrm{Neu} 5 \mathrm{Ac}$, whereas in both $\beta$ compounds the $\mathrm{C}=\mathrm{O}$ bond is found to be nearly eclipsed with the anomeric $\mathrm{C}-\mathrm{O}$ bond. The preference for a planar conformation of the $\mathrm{O}-\mathrm{C}-\mathrm{C}=\mathrm{O}$ fragment is also known to occur in $\alpha$-hydroxy carboxylic acids (Kanters, Kroon, Peerdeman \& Schoone, 1967; Kroon, 1982; Newton \& Jeffrey, 1977). Due to the acetal group, two such fragments occur in neuraminic acids so that there are two alternatives for the planarity. In the $\alpha$ form the carboxyl group is probably not aligned with the anomeric $\mathrm{C}-\mathrm{O}$ bond, as in the $\beta$ compounds, because this would introduce steric repulsion with $\mathrm{C}(6)-\mathrm{H}(6)$ and $\mathrm{C}(4)-\mathrm{H}(4)$.

The $N$-acetyl group is essentially planar. The r.m.s. deviation of the atoms $C(13), C(12), O(12)$ and $N(5)$ from their least-squares plane is $0.001 \AA$, the deviation of atom $\mathrm{C}(5)$ from that plane is only $0 \cdot 202$ (5) $\AA$. In all three neuraminic acids the $N$ acetyl group adopts the $Z$ conformation of the peptide bond $[\mathrm{C}(12)=\mathrm{O}(12)$ is eclipsed with $\mathrm{N}(5)-\mathrm{C}(5)]$ and the $\mathrm{N}(5)-\mathrm{H}(25)$ bond is in trans position to the ring $\mathrm{C}(5)-\mathrm{H}(5)$ bond. In the latter torsional parameter differences of more than $20^{\circ}$ occur which can be

attributed to the intramolecular $\mathrm{O}(7)-\mathrm{H}(17) \cdots \mathrm{O}(12)$ hydrogen bond which occurs in 1,2diMe $\alpha$ Neu5Ac and $1 \mathrm{Me} \beta \mathrm{Neu} 5 \mathrm{Ac}$ and produces a larger $\mathrm{C}(4)$ -$\mathrm{C}(5)-\mathrm{N}(5)-\mathrm{C}(12)$ torsion angle than in the case of $\beta \mathrm{Neu} 5 \mathrm{Ac}$ where this hydrogen bond is absent.

The overall conformation of the glycerol side chain is the same for all three compounds as far as non-H atoms are concerned. In $1,2 \mathrm{diMe} \alpha \mathrm{Neu5Ac}$, in addition to $\mathrm{O}(7)-\mathrm{H}(17) \cdots \mathrm{O}(12)$, another intramolecular hydrogen bond involving the glycerol side chain is directed toward the carboxyl group $[\mathrm{O}(8)-\mathrm{H}(18) \cdots \mathrm{O}(1)]$. In the $\beta$ forms this hydrogen bond cannot occur because of the equatorial position of the carboxyl group. As in the crystal structure of $\beta$ Neu5Ac, neither of these hydrogen bonds occurs, the preference for this particular conformation of the glycerol side chain seems not to depend on intramolecular hydrogen bonding, although it is likely that in solution they will contribute to the rigidity of the molecule. The conformation of the glycerol side chain is consistent with ${ }^{3} J$ coupling constants obtained by ${ }^{1} \mathrm{H}$ NMR measurements of $\beta \mathrm{Neu} 5 \mathrm{Ac}$ in aqueous solution (Brown, Brey \& Weltner, 1975) although in that paper another conformation is proposed. From $T_{1}$ relaxation times obtained from ${ }^{13} \mathrm{C}$

* The symmetry operation is performed on the acceptors ( $A$ ). The first three digits specify the lattice translations. The last digit indicates one of the following symmetry operations: (1) $x, y, z ;(2) \frac{1}{2}+x, \frac{1}{2}-y,-z ;(3)-x, \frac{1}{2}+y$, $\frac{1}{2}-z$; (4) $\frac{1}{2}-x,-y, \frac{1}{2}+z$ (e.g. $545 \cdot 3$ is $-b$ from 555.3).

Fig. 2. View of the structure down the $a$ axis. The $\mathrm{C}, \mathrm{O}, \mathrm{N}$ and H atoms are represented by white, black, dotted and small spheres, respectively.

NMR data (Czarniecki \& Thornton, 1977) on $\alpha$ and $\beta$ forms of Neu5Ac in aqueous solution, low mobility was found around the $C(6)-C(7)$ and $C(7)-C(8)$ bonds. The persistence of this particular glycerol side-chain conformation in crystals is in agreement with these findings.

The hydrogen-bonding geometries in the crystal structure of $1,2 \mathrm{diMe} \alpha \mathrm{Neu} 5 \mathrm{Ac}$ are listed in Table 3. Every molecule is surrounded by six hydrogenbonded neighbours. A two-dimensional network is
formed by hydrogen bonds in the [100] and [110] directions. The contacts in the [001] direction are hydrophobic in nature. Fig. 2 gives a view of the structure down a.

The authors thank Dr P. van der Sluis for growing the crystals and Dr J. P. Kamerling for supplying the material.
