#### Abstract

Tetrapotassium dibromide oxide, $\mathrm{K}_{4} \mathrm{OBr}_{2}$, $M_{r}=332 \cdot 2$, tetragonal, $I 4 / \mathrm{mmm}, \quad a=5 \cdot 145$ (2), $c=16.527(4) \AA, \quad V=437.49 \AA^{3}, \quad Z=2, \quad D_{x}=$ $2.522 \mathrm{~g} \mathrm{~cm}^{-3}, \quad \lambda($ Mo $K \alpha)=0.71069 \AA, \quad \mu=$ $109.11 \mathrm{~cm}^{-1}, F(000)=308, T=294 \mathrm{~K}, \quad R=0.0428$ for 197 unique reflections with $F_{o}>2 \sigma\left(F_{o}\right)$. The yellow compound crystallizes in the anti- $\mathrm{K}_{2} \mathrm{NiF}_{4}$ structure type and is isotypic with the colourless $\mathrm{Na}_{4} \mathrm{OI}_{2}$.

Introduction. Recently we described the preparation of $\mathrm{Na}_{3} \mathrm{OCl}$ and of $\mathrm{Na}_{3} \mathrm{OBr}$ (Sabrowsky, Paszkowski, Reddig \& Vogt, 1988) and the crystal structure of $\mathrm{Na}_{4} \mathrm{OI}_{2}$ (Sabrowsky, Hippler, Sitta, Vogt \& Walz, 1990) as part of our investigations into the existence of ternary alkali-metal chalcogenide halides. $\mathrm{Na}_{3} \mathrm{OCl}$ and $\mathrm{Na}_{3} \mathrm{OBr}$ crystallize in the antiperovskite structure type whereas $\mathrm{Na}_{4} \mathrm{OI}_{2}$ forms crystals with the anti- $\mathrm{K}_{2} \mathrm{NiF}_{4}$ structure. We have now succeeded in preparing single crystals of $\mathrm{K}_{4} \mathrm{OBr}_{2}$ and determining their structure. The results are presented here.

Experimental. Polycrystalline samples of $\mathrm{K}_{4} \mathrm{OBr}_{2}$ can be obtained by sintering a corresponding stoichiometric mixture of $\mathrm{K}_{2} \mathrm{O}$ and KBr in closed silver or corundum crucibles between 573 and 623 K in vacuum. Well shaped yellow single crystals of $\mathrm{K}_{4} \mathrm{OBr}_{2}$ were grown from these mixtures at 623 K in silver crucibles. The crystals are very sensitive to air and moisture. $D_{m}$ was not measured. A crystal with the approximate dimensions $0.2 \times 0.3 \times 0.05 \mathrm{~mm}$ was used for the data collection. The unit-cell parameters were determined by least-squares treatment of the adjusted angular settings of 25 diffraction maxima in the $\theta$ range $13.5-18^{\circ}$. The intensity measurements were carried out on a Philips PW 1100/15 four-circle diffractometer at 294 K with graphitemonochromated Mo $K \alpha$ radiation applying the $\omega-2 \theta$ scan technique. A total of 683 reflections were collected in the range $3 \leq 2 \theta \leq 60^{\circ}(h:-7 \rightarrow 7, k: 0 \rightarrow$

7, $l: 0 \rightarrow 19$ ). Three strong reflections monitored periodically exhibited no significant intensity variation. The data were corrected for Lorentz and polarization effects, leading to 197 unique reflections (nine unobserved unique reflections) with $F_{o}>2 \sigma\left(F_{o}\right)$ ( $R_{\text {int }}=0.0291$ ). Absorption was corrected empirically by final $F_{o}-F_{c}$ comparison using DIFABS (Walker \& Stuart, 1983) (min. correction: 0.758; max. correction: $1 \cdot 560$ ). The structural model was verified by Patterson and Fourier methods using SHELX76 (Sheldrick, 1976). Least-squares refinement on $F$ with anisotropic thermal parameters led to the atomic parameters given in Table 1.* Final $R=0.0428, w R$ $=0.0339,\left\{w=k /\left[\sigma^{2}(F)+g F^{2}\right] ; k=1 \cdot 3973, g=0.0\right\}$, $(\Delta / \sigma)_{\max }=0.03, \quad(\Delta \rho)_{\max }=1.33, \quad(\Delta \rho)_{\min }=$ $-1.62 \mathrm{e} \AA^{-3}$. Atomic scattering factors and $f^{\prime}, f^{\prime \prime}$ values were taken from International Tables for X-ray Crystallography (1974).

Discussion. $\mathrm{K}_{4} \mathrm{OBr}_{2}$ crystallizes in the anti- $\mathrm{K}_{2} \mathrm{NiF}_{4}$ structure type (Fig. 1) and is isotypic with $\mathrm{Na}_{4} \mathrm{OI}_{2}$. The structure can be derived from the anti-perovskite structure as we have shown earlier (Sabrowsky, Hippler, Sitta, Vogt \& Walz, 1990). The oxygen anion is coordinated octahedrally by six potassium ions. The structure involves two crystallographically different potassium ions, both octahedrally coordinated. $K(1)$ is surrounded by two oxygen and four bromide ions, $\mathrm{K}(2)$ has one oxygen and five bromide neighbours. The coordination of the bromide anions is ninefold. A $\mathrm{Br}^{-}$anion is surrounded by a square plane of four $\mathrm{K}^{+}$ions approximately in the plane $z$ $=0.15$. Above this plane a fifth $\mathrm{K}^{+}$ion completes a square pyramid about the $\mathrm{Br}^{-}$anion and below it a further square plane of four $\mathrm{K}^{+}$ions, twisted about $z$ by $45^{\circ}$ relative to the first, also participates in the

coordination polyhedron of the $\mathrm{Br}^{-}$anion (for atomic coordinates and interatomic distances see Tables 1 and 2).

Related to the sum of the molar volumes of $\mathrm{K}_{2} \mathrm{O}$ ( $40.4 \mathrm{~cm}^{3}$ ) and $\mathrm{KBr}\left(43.3 \mathrm{~cm}^{3}\right.$ ), a volume dilation of $+3.8 \%$ is observed for the formation of $\mathrm{K}_{4} \mathrm{OBr}_{2}\left(V_{m}\right.$ $=131.8 \mathrm{~cm}^{3} \mathrm{~mol}^{-1}$ ).

Besides $\mathrm{K}_{4} \mathrm{OBr}_{2}$ the perovskite-phase $\mathrm{K}_{3} \mathrm{OBr}[a=$ $5 \cdot 22$ (4) $\AA]$ (Hippler, Sitta, Vogt \& Sabrowsky, 1989) also exists, as expected by the rules given by Goldschmidt (1926). The coexistence of $\mathrm{K}_{4} \mathrm{OBr}_{2}$ and $\mathrm{K}_{3} \mathrm{OBr}$ can be explained by an estimation of the lattice energies ( $U_{L}$ ) for these compounds. Using the Madelung constant $\left[M\left(\mathrm{~K}_{2} \mathrm{NiF}_{4}\right)=7.47461\right.$ (Hoppe \& Wald, 1989)] and the Born-Landé equation $U_{L}=$ $-\left(M e^{2} / 4 \pi \varepsilon_{o} R\right) N_{L}(1-1 / n) \quad$ with $\quad R=R(\mathrm{O}-\mathrm{K})=$ $2.57 \AA$ and the Born exponent $n=9$, the lattice
energy value for $\mathrm{K}_{4} \mathrm{OBr}_{2}$ is $U_{L}\left(\mathrm{~K}_{4} \mathrm{OBr}_{2}\right)=$ $-3591.8 \mathrm{~kJ} \mathrm{~mol}^{-1} \quad$ whereas $\quad U_{L}(\mathrm{KBr})=$ $-658.3 \mathrm{~kJ} \mathrm{~mol}^{-1}[R(\mathrm{KBr})=3.30 \AA, \quad n=9.5]$ and $U_{L}\left(\mathrm{~K}_{2} \mathrm{O}\right)=-2206.9 \mathrm{~kJ} \mathrm{~mol}^{-1}[R(\mathrm{O}-\mathrm{K})=2.79 \AA, n$ $=8 \cdot 3]$. This leads to a difference of $-68.3 \mathrm{~kJ} \mathrm{~mol}^{-1}$ for the formation of $\mathrm{K}_{4} \mathrm{OBr}_{2}$ in comparison with $\mathrm{K}_{2} \mathrm{O}+2 \mathrm{KBr}$.

For $\mathrm{K}_{3} \mathrm{OBr}$ the lattice energy is calculated to be $U_{L}=-2920.0 \mathrm{~kJ} \mathrm{~mol}^{-1}$ using the Madelung constant $M\left(\mathrm{~K}_{3} \mathrm{OBr}\right)=6 \cdot 18872$ (Hoppe, 1956; Ladd \& Lee, 1965), $R(\mathrm{O}-\mathrm{K})=2.61 \AA, n=8.8$. Taking the above values for $\mathrm{K}_{2} \mathrm{O}$ and KBr , the difference relative to $\mathrm{K}_{3} \mathrm{OBr}$ is $-54.8 \mathrm{~kJ} \mathrm{~mol}^{-1}$.

These calculations show that both compounds are stable against decomposition to KBr and $\mathrm{K}_{2} \mathrm{O}$. It is mainly a question of the $\mathrm{K}_{2} \mathrm{O} / \mathrm{KBr}$ ratio and the reaction temperature which determines whether $\mathrm{K}_{3} \mathrm{OBr}$ or $\mathrm{K}_{4} \mathrm{OBr}_{2}$ is formed.

An interesting difference between the sodium and the potassium compounds involves the colours. All sodium compounds are colourless whereas the potassium compounds show colours ranging from yellow to orange. To discover the reason for this difference in colour, physical measurements and further preparation of comparable compounds with rubidium and caesium are already in progress.

Support of this work by the Deutsche Forschungsgemeinschaft and the Fonds der Chemischen Industrie is gratefully acknowledged.
