Structure of a Nucleoside Analogue, 3'-Deoxy-3'-fluorothymidine*

BY D. H. EVERAERT, O. M. PEETERS, N. M. BLATON AND C. J. DE RANTER†

Laboratorium voor Analytische Chemie en Medicinale Fysicochemie, Instituut voor Farmaceutische Wetenschappen, Katholieke Universiteit Leuven, Van Evenstraat 4, B-3000 Leuven, Belgium

(Received 25 September 1989; accepted 16 January 1990)

Abstract. 1-(2,3-Dideoxy-3-fluoro- β -D-erythro-pentofuranosyl)thymine, $C_{10}H_{13}FN_2O_4$, $M_r = 244.22$, monoclinic, $P2_1$, $a = 6.408$ (14), $b = 18.716$ (26), $c = 9.329$ (7) Å, $\beta = 98.4$ (1) $^{\circ}$, $V = 1107$ (3) Å 3 , $Z = 4$, $D_m = 1.46$, $D_x = 1.465$ Mg m $^{-3}$, graphite-monochromated Mo $K\alpha$ radiation, $\lambda = 0.71073$ Å, $\mu = 0.1169$ mm $^{-1}$, $F(000) = 512$, $T = 298$ K, final $R = 0.035$ for 1425 unique observed reflections. The asymmetric unit contains two molecules (*A* and *B*). For molecule *A*: the *N*-glycosidic torsion angle χ has a value of -138.4 (5) $^{\circ}$ in the *anti* range; the sugar pucker is 2E with $P = 164$ (1) $^{\circ}$ and $\psi_m = 36$ (1) $^{\circ}$ and the C4'—C5' conformation is +sc with $\gamma = 50.2$ (7) $^{\circ}$. For molecule *B*: the *N*-glycosidic torsion angle χ has a value of -159.6 (5) $^{\circ}$ in the *anti* range; the sugar pucker is 2T_3 with $P = 169$ (1) $^{\circ}$ and $\psi_m = 32$ (1) $^{\circ}$ and the C4'—C5' conformation is +sc with $\gamma = 52.8$ (7) $^{\circ}$. The conformational parameters are in

accordance with the IUPAC–IUB Joint Commission on Biochemical Nomenclature [*Pure Appl. Chem.* (1983), **55**, 1273–1280] guidelines. Base-pair formation occurs between the two molecules *A* and *B*.

Introduction. This structure was determined as part of an investigation of potentially antiviral nucleoside analogues, with particular reference to possible anti-AIDS compounds.

Experimental. Colourless prismatic crystals obtained at room temperature from a methanol–ether solution, dimensions $\sim 0.6 \times 0.3 \times 0.2$ mm. Density measured by flotation in *n*-heptane/CCl₄. Stadi-4 computer-controlled four-circle diffractometer, graphite-monochromated Mo $K\alpha$ radiation, $\omega/2\theta$ scan technique ($2\theta_{\max} = 50^{\circ}$, $-8 \leq h \leq 0$, $-22 \leq k \leq 22$, $-11 \leq l \leq 11$). Cell dimensions by least-squares refinement of the setting angles of 24 reflections with $17 < 2\theta < 25^{\circ}$, space group $P2_1$ from systematic absences $0k0$ for k odd. Four standard reflections ($\bar{1}0\bar{3}$, $\bar{1}02$, $\bar{2}51$, $0\bar{3}\bar{2}$) monitored every 120 min showed no significant decrease in intensity per hour, 4288

* Structural Studies of Modified Nucleosides. Part II. Part I: Van Aerschot, Everaert, Peeters, Blaton, De Ranter & Herdewijn (1990).

† To whom correspondence should be addressed.

reflections measured, 2021 unique reflections ($R_{\text{int}} = 0.020$) of which 1428 considered as observed [$F > 4\sigma(F)$]. Three reflections (040, 100, 102) badly affected by extinction were eliminated. Lorentz-polarization corrections, no absorption corrections, scattering factors from *International Tables for X-ray Crystallography* (1974) and Stewart, Davidson & Simpson (1965) (for H). The structure was solved by *MULTAN82* (Main, Fiske, Hull, Lessinger, Germain, Declercq & Woolfson, 1982). The *E* map calculated from the solution with the best figure of merit revealed 17 of the 34 non-H atoms in the asymmetric unit. The remaining atoms were obtained from a subsequent Fourier synthesis. A difference synthesis revealed the position of all H atoms, which were refined with fixed isotropic temperature factors ($B_{\text{eq}} = 4 \text{ \AA}^2$). All other atoms were refined anisotropically on *F* by full-matrix least squares. The refinement converged at $R = 0.035$, $wR = 0.045$, $S = 0.284$. $w = (C_0 + C_1|F_o| + C_2|F_o|^2 + C_3|F_o|^3)^{-1}$, where $C_0 = 1000$, $C_1 = 1$, $C_2 = 0.00004$, $C_3 = 0.000009$. 385 refined parameters, maximum shift/e.s.d. = 0.03, minimum and maximum electron density -0.194 and 0.152 e \AA^{-3} . The number of reflections per refined variable was $1425/385 = 3.7$. All calculations were performed on a PDP 11/73 micro-computer using *SDP/PDP* (Enraf-Nonius, 1982) and *PAST* (Nardelli, 1983).

* Parameter kept fixed for origin definition.

Discussion. An *ORTEP* view (Johnson, 1976) of molecules *A* and *B* with the atomic numbering scheme is shown in Fig. 1.* The final fractional atomic coordinates are given in Table 1. Bond lengths, bond angles and some selected torsion angles are given in Table 2. Fig. 2 shows the intramolecular hydrogen bonds and the classical intermolecular hydrogen bonds. Table 3 gives the geometry of all hydrogen bonds. Between the two molecules *A* and *B* there is base-pair formation including two so-called 'cyclic' N3—H···O4 hydrogen bonds ($-x + 1, y + \frac{1}{2}, -z + 1; -x + 1, y - \frac{1}{2}, -z + 1$) in order to produce a stable base pair; the geometrical characteristics of the hydrogen bonds involved in this base-base interaction are all within the normal limits (Saenger, 1984).

Both O5'A and O5'B donate their H13 to the O2 of a translational symmetry equivalent ($x - 1, y, z - 1; x - 1, y, z$). These hydrogen bonds create a net-

* Lists of structure factors, anisotropic thermal parameters, bond lengths and angles involving H atoms, least-squares planes, and H-atom parameters have been deposited with the British Library Document Supply Centre as Supplementary Publication No. SUP 52900 (21 pp.). work along the diagonal between the *a* and *c* crystallographic axes. Each molecule also has one intramolecular hydrogen bond: C6—H···O5'. This non-classical bond can reasonably be described as a hydrogen bond according to Taylor & Kennard (1982), and favours the +sc conformer with anti-oriented base moieties over the other two possible staggered forms (-sc and ap).

There is no conformational similarity between the title compound and AZT (Dyer, Low, Tollin, Wilson
