Ammonium ion

N(5)	10054 (8)	2558 (3)	3829 (2)	3·9 (3)
------	-----------	----------	----------	---------

C₆N₈O₈²⁻ anion and one NH₄⁺ cation. The rings are planar within 0·03 Å. The nitro groups are twisted out of the ring plane by 18·9 (1) and 21·6 (1)^o. The ammonium ion is hydrogen bonded to four different molecules. Two H atoms make hydrogen bonds to ring N atoms and two to O atoms. This rigid structure is compatible with the relatively high decomposition temperature (without melting) of 523–533 K. Bond distances are very similar to those found in biimidazole (Cromer, Ryan & Storm, 1987) and in tetranitrobiimidazole dihydrate (Cromer & Storm, 1990).

Related literature. References to structures of other small high-energy molecules are given by Cromer, Hall, Lee & Ryan (1988).

$wR = 0\cdot046$ for 1511 observed reflections. The title compound contains a bicyclic α -D-pyranoside system that has a *cis* ring junction with the δ -lactam ring. The molecules are held in the crystal by hydrogen bonds of the O—H···O type or N—H···O type. The O···O distances range from 2·707 (3) to 2·875 (4) Å, while the N···O distance is 2·876 (4) Å.

Experimental. As part of a general strategy towards the synthesis of indole alkaloids such as ajmalicine (1), and some of its natural stereoisomers, intermediate (2) was obtained. Although the structure of the olefinic precursor (3a), derived in nine steps from D-glucose, had already been confirmed by X-ray analysis (Léger, Bélanger-Gariépy, Hanessian & Brisse, 1984), further transformations to (2) necessitated stereochemical assignment by X-ray crystallography. In this paper, we report the crystal structure of (2) (m.p. 434–436 K, ether-chloroform) by X-ray analysis.

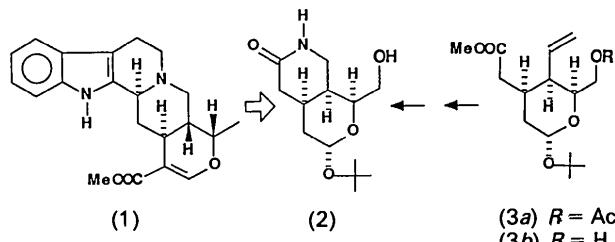

Plate-shape crystal of $C_{13}H_{23}NO_4 \cdot H_2O$ bounded by {001}, {101}, {111}; dimensions $0.11 \times 0.14 \times 0.47$ mm. Unit cell from 25 well centered reflections in the range $20 \leq \theta \leq 23^\circ$. Nonius CAD-4 diffractometer, graphite-monochromatized Cu $K\bar{\alpha}$ radiation, ω scan technique, $\Delta\omega = (1.00 + 0.14\tan\theta)^\circ$, $2\theta_{\max} = 140.0^\circ$ ($-19 \leq h \leq 19$, $0 \leq k \leq 8$, $-17 \leq l \leq 17$). Orientation monitored every 200 measurements, intensity checked every hour using seven standard reflections, largest intensity fluctuation 1.0%. 3145 measured reflections, 1698 reflections (hkl , $\bar{h}\bar{k}\bar{l}$) retained after averaging of equivalent reflections to Laue 2 symmetry ($R_{\text{int}} 0.043$) of which 1515 where $I \geq 1.96\sigma(I)$ retained for structure determination and refinement. Lp correction, no absorption correction.

The structure was solved by direct methods (MULTAN80)* and difference Fourier calculations (SHELX). Full-matrix least-squares refinement based on F , all non-H atoms anisotropic. All H atoms found on difference Fourier synthesis. Function minimized: $\sum w(|F_o| - |F_c|)^2$. In the last refinement cycles, four reflections (020, $\bar{1}31$, $\bar{1}32$ and $\bar{2}03$) with high residuals were given zero weight because of suspected errors in intensity measurements. Final $R = 0.047$, $wR = 0.046$ {weights derived from the counting statistics $w = 1/[\sigma^2(F) + 0.0001F^2]$ } and $S = 2.145$ for 271 parameters. Maximum $(\Delta/\sigma) = 0.35$, average $(\Delta/\sigma) = 0.03$, residual electron den-
