Crystal Chemistry of *cyclo*-Hexaphosphates. XII. Structure of Ammonium Calcium *cyclo*-Hexaphosphate Hexahydrate

BY M. T. AVERBUCH-POUCHOT

Laboratoire de cristallographie, associé à l'Université J. Fourier, CNRS, 166X, 38042 Grenoble CEDEX, France

(Received 8 December 1989; accepted 26 February 1990)

Abstract. $\text{Ca}_2(\text{NH}_4)_2\text{P}_6\text{O}_{18} \cdot 6\text{H}_2\text{O}$, $M_r = 698 \cdot 154$, orthorhombic, $P2_12_12$, $a = 12 \cdot 821$, $b = 12 \cdot 537$ (6), $c = 7 \cdot 029$ (2) Å, $V = 1130$ (1) Å³, $Z = 2$, $D_x = 2 \cdot 052$ Mg m⁻³, $\lambda(\text{Mo } K\alpha) = 0 \cdot 7107$ Å, $\mu = 1 \cdot 021$ mm⁻¹, $F(000) = 712$, $T = 294$ K, final $R = 0 \cdot 035$ for 1667 reflections. This compound is the first reported example of a P_6O_{18} ring anion with twofold internal symmetry. The P_6O_{18} ring anions and one of the ammonium groups alternate along the twofold axis, parallel to the c direction. The second ammonium group, also located on a binary axis, and the Ca atoms interconnect these rows.

Introduction. This work is part of a systematic investigation of monovalent-divalent cation *cyclo*-hexaphosphates. Several structure types have already been described for such compounds: $\text{Mn}_2\text{Li}_2\text{P}_6\text{O}_{18} \cdot 10\text{H}_2\text{O}$ (Averbuch-Pouchot, 1989), $\text{Cd}_2\text{Na}_2\text{P}_6\text{O}_{18} \cdot 14\text{H}_2\text{O}$ (Averbuch-Pouchot, 1990), $\text{Ca}_2\text{Li}_2\text{P}_6\text{O}_{18} \cdot 8\text{H}_2\text{O}$ (Averbuch-Pouchot & Durif, 1990a), $\text{Cu}_2(\text{NH}_4)_2\text{P}_6\text{O}_{18} \cdot 8\text{H}_2\text{O}$ (Averbuch-Pouchot & Durif, 1990b). $\text{Ca}_2(\text{NH}_4)_2\text{P}_6\text{O}_{18} \cdot 6\text{H}_2\text{O}$, described in the present work, is the fifth structure type observed so far in this area of *cyclo*-hexaphosphate chemistry.

Experimental. Single crystals of the title compound were prepared by adding solid gypsum to an aqueous

solution of ammonium *cyclo*-hexaphosphate at room temperature. After some days, large orthorhombic prisms of $\text{Ca}_2(\text{NH}_4)_2\text{P}_6\text{O}_{18} \cdot 6\text{H}_2\text{O}$ appear in the solution.

Crystal size: $0 \cdot 26 \times 0 \cdot 16 \times 0 \cdot 19$ mm. Density not measured. Philips PW1100 diffractometer, graphite monochromator. 17 reflections ($11 \cdot 0 < \theta < 13 \cdot 0^\circ$) for refining unit-cell dimensions. ω scan, scan width: $1 \cdot 10^\circ$, scan speed: $0 \cdot 02^\circ$ s⁻¹, total background measuring time: 6 s. 3223 reflections collected ($3 < \theta < 30^\circ$), $\pm h, k, l$, $h_{\max} = 18$, $k_{\max} = 17$, $l_{\max} = 9$. Two orientation and intensity-control reflections (640 and 640) measured every 2 h without any significant variation. 1667 reflections after averaging Friedel pairs ($R_{\text{int}} = 0 \cdot 022$). Lorentz and polarization corrections, no absorption correction. Structure solved by direct methods (*MULTAN77*; Main, Hull, Lessinger, Germain & Woolfson, 1977). H atoms located by difference Fourier synthesis. Anisotropic full-matrix refinement (on F), isotropic for H atoms. Unit weights. Final refinement using 1667 reflections (no rejection). Final $R = 0 \cdot 035$ ($wR = 0 \cdot 041$), $S = 1 \cdot 278$, $\Delta/\sigma_{\max} = 0 \cdot 04$. Maximum peak height in the final difference Fourier map $0 \cdot 280$ e Å⁻³. No secondary-extinction correction. Scattering factors for neutral atoms and f' , f'' from *International Tables for X-ray Crystallography* (1974, Vol. IV, Table 2.2B). Enraf-

Discussion. Table 1 gives the final atomic coordinates.* The P_6O_{18} ring anion is located about the twofold axis parallel to the *c* axis. Table 2 gives the main geometrical features of the anion. The existence of P_6O_{18} groups with $\bar{1}$, $\bar{3}$, 3 and *m* internal symmetry has already been observed. The title compound is the first example of twofold internal symmetry in a condensed anion of this type. In spite of this internal symmetry the ring is far from regular. The P—P—P angles vary between 87.77 and 116.10°. The P(2)—P(1)—P(3) angle observed here (87.77°) is the smallest reported for a P_6O_{18} group.

The two ammonium groups are also located on the twofold axes. The first, N(1), is coordinated to ten O atoms and two water molecules. The second, N(2), has only eight neighbours: four water molecules and four O atoms. It is worth noting that six of the bonding O atoms, O(*L*), of the condensed phosphoric anion, make up part of the N(1) coordination polyhedron, which is rare in condensed phosphate crystal chemistry.

* Lists of structure factors and anisotropic thermal parameters have been deposited with the British Library Document Supply Centre as Supplementary Publication No. SUP 53085 (17 pp.). ($\text{NH}_4\text{Mo}_3\text{O}_9$, an Ammonium Molybdenum Bronze)

BY KLAUS-JÜRGEN RANGE,* KARL BAUER AND ULRICH KLEMENT

Institute of Inorganic Chemistry, University of Regensburg, Universitätsstrasse 31, D-8400 Regensburg, Federal Republic of Germany

(Received 27 October 1989; accepted 16 February 1990)

Abstract. Ammonium trimolybdate(V,2VI), $M_r = 449.85$, monoclinic, $C2/m$, $a = 14.819(4)$, $b = 7.708(1)$, $c = 6.386(2)$ Å, $\beta = 93.56(3)^\circ$, $V = 728.0$ Å 3 , $Z = 4$, $D_x = 4.10$ Mg m $^{-3}$, $\lambda(\text{Mo } K\alpha) = 0.71073$ Å, $\mu = 5.0$ mm $^{-1}$, $F(000) = 836$, $T = 296$ K. The structure was refined to $R = 0.074$ for 882 absorption-corrected reflections. The bronze, prepared by hydrothermal decomposition of ammonium heptamolybdate, contains units of six edge-shared MoO_6 octahedra [$\text{Mo}(1)–\text{O} = 1.67$ –2.29, $\text{Mo}(2)–\text{O} = 1.68$ –2.38 Å] which share vertices along [010] and [001] to form infinite layers. The ammonium ions completely occupy positions with an irregular eight-fold coordination ($\text{N}–\text{O} = 2.74$ –3.14 Å) between the layers.

Introduction. NH_3 is a mild reducing agent for transition metal–oxygen compounds. This has been

demonstrated in a detailed study of the closed-system thermal decomposition of NH_4VO_3 (Range & Zintl, 1983; Range, Zintl & Heyns, 1988) and $(\text{NH}_4)_2\text{V}_6\text{O}_{16}$ (Range, Eglmeier, Heyns & De Waal, 1990). Redox reactions can also occur in the system NH_3 – MoO_3 – H_2O . The present paper describes the hydrothermal synthesis and structure refinement of a new ammonium molybdenum bronze, $(\text{NH}_4)\text{Mo}_3\text{O}_9$.

Experimental. $(\text{NH}_4)\text{Mo}_3\text{O}_9$ was prepared by hydrothermal decomposition of ammonium heptamolybdate, $(\text{NH}_4)_6\text{Mo}_7\text{O}_{24} \cdot 2\text{H}_2\text{O}$ (silver ampoule, 500 bar, 625 K, 72 h, heating rate 5 K min $^{-1}$, cooling rate 0.5 K min $^{-1}$). The reaction product consisted of a mixture of black needles (MoO_2 , main product) and bronze-coloured crystals with nearly rectangular shape. Chemical analysis of selected bronze-coloured crystals (NH_4 found: 3.98, 4.12%; calculated: 4.01%) and EDX (only Mo, no Ag found) pointed to the stoichiometry $(\text{NH}_4)\text{Mo}_3\text{O}_9$.
