

for the H atoms are from Stewart, Davidson & Simpson (1965). The values used to calculate the linear absorption coefficient are from *International Tables for X-ray Crystallography* (1974). Positional and thermal parameters for non-H atoms are listed in Table 1,\* while the bond lengths and angles for the non-H atoms are listed in Table 2. The atom-labelling scheme is shown in Fig. 1. The least-squares-planes program was supplied by Cordes (1983); other computer programs are listed in Gadol & Davis (1982).

**Related literature.** (1) is a bicyclic intermediate in a synthetic route aimed at preparing the tricyclic carbon framework of the taxane diterpenes (Martin, White & Wagner, 1982). The structures of related [5.3.1]undecenes have been reported (Lynch, Fishpaugh, Martin & Davis, 1990; Lynch, Tanaka, Fishpaugh, Martin & Davis, 1990). The alkene moiety in these structures is also highly distorted.

\* Lists of structure factors, anisotropic thermal parameters, torsion angles, least-squares planes, unit-cell packing diagram and H-atom parameters have been deposited with the British Library Document Supply Centre as Supplementary Publication No. SUP 53032 (21 pp.). Copies may be obtained through The Technical Editor, International Union of Crystallography, 5 Abbey Square, Chester CH1 2HU, England.

Funding for this project was supplied by the Robert A. Welch Foundation (F-652) and the National Institutes of Health (CA 37929).

## Structure of the Eudesmanolide Gazaniolide\*

BY MICHAEL A. JANUSA, MARK S. JEANSONNE, FRANK R. FRONCZEK AND STEVEN F. WATKINS†

Department of Chemistry, Louisiana State University, Baton Rouge, Louisiana 70803, USA

(Received 9 March 1990; accepted 21 May 1990)

**Abstract.**  $C_{15}H_{18}O_2$ ,  $M_r = 230.31$ , orthorhombic,  $P2_12_12_1$ ,  $a = 7.129(1)$ ,  $b = 11.126(2)$ ,  $c = 16.112(2)$  Å,  $V = 1278.0(6)$  Å $^3$ ,  $Z = 4$ ,  $D_x = 1.197$  g cm $^{-3}$ , at 293(1) K,  $\lambda(Cu K\alpha) = 1.54184$  Å,  $\mu = 5.8$  cm $^{-1}$ ,  $F(000) = 496$ , 1535 unique reflections measured, final  $R = 0.038$  over 1217 reflections having  $I > 1.0\sigma(I)$ . This sesquiterpene lactone of the eudesmanolide class, extracted from the roots of the plant *Rudbeckia subtomentosa*, has an unusual 1,3-cyclohexadiene ring which is highly susceptible to air

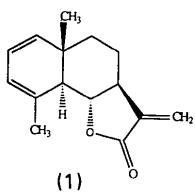

oxidation. The two six-membered rings are *trans*-fused, with the saturated ring in the chair conformation and the ring containing the diene in the half-chair conformation. The pseudo twofold axis of the half chair bisects the diene, and the torsion angle about the central bond of the diene is  $-16.1(4)^\circ$ .

**Experimental.** A colorless, nearly isometric crystal of gazaniolide, (1),  $0.35 \times 0.38 \times 0.40$  mm, was mounted in a glass capillary in random orientation on an Enraf–Nonius CAD-4 diffractometer equipped with a graphite crystal incident beam monochromator. Cell constants were obtained from least-squares refinement of the setting angles of 25 reflections in the range  $21 < \theta < 27^\circ$ . From systematic absences

\* Chemical Abstracts name: [3aS-(3a $\alpha$ ,5a $\beta$ ,9a $\alpha$ ,9b $\beta$ ]-3a,4,5a,9a,9b-hexahydro-5a,9-dimethyl-3-methylenenaphtho[1,2-b]-furan-2(3H)-one.

† Author to whom correspondence should be addressed.

( $h00$ ,  $h$  odd,  $0k0$ ,  $k$  odd,  $00l$ , odd) the space group was determined to be  $P2_12_12_1$ .

Two octants of data were collected using the  $\theta-2\theta$  scan technique, variable scan rates from 0.72 to  $3.30^\circ \text{ min}^{-1}$  ( $h = 0$  to 8,  $k = 0$  to 13,  $l = -20$  to 20) to a maximum  $2\theta$  of  $150^\circ$ . A total of 2978 reflections was measured, of which 1535 were unique and not systematically absent. Redundant reflections were averaged with  $R_{\text{int}} = 0.025$ . Three representative reflections (200, 020, 006) were measured every 10 000 s, and only random variations were observed. Lorentz and polarization corrections were applied. An empirical absorption correction based on a series of  $\psi$  scans was applied to the data; relative transmission coefficients ranged from 0.949 to 0.998 with an average value of 0.975.

The structure was solved by direct methods (Mair, Fiske, Hull, Lessinger, Germain, Declercq & Woolfson, 1982). Hydrogen atoms were located from difference maps and refined isotropically. The structure was refined by full-matrix least squares where the function minimized was  $\sum w(|F_o| - |F_c|)^2$  and the weight is  $w = 4F_o^2/\sigma^2(F_o^2)$ . The variance of the structure amplitude is defined as  $\sigma^2(F_o^2) = [S^2(C + R^2B) + (pF_o^2)]/Lp^2$  where  $S$  is the scan rate,  $C$  is the total integrated peak count,  $R$  is the ratio of scan time to background counting time,  $B$  is the total background count,  $Lp$  is the Lorentz-polarization factor, and  $p$  was set to 0.020.

Scattering factors, including anomalous-dispersion terms, were taken from the *International Tables for X-ray Crystallography* (1974, Vol. IV). Only the 1217 reflections having  $I > 1\sigma(I)$  were used in the refinement. The final cycle of refinement included 227 variable parameters and converged (largest  $\Delta/\sigma = 0.03$ ) with  $R = 0.038$ ,  $wR = 0.038$ ,  $R(\text{all}) = 0.057$ , and  $S = 1.285$ . A secondary-extinction coefficient refined to a value of  $g = 3.31(12) \times 10^{-6}$ , where the correction factor  $(1 + gI_e)^{-1}$  was applied to  $F_c$ . There were no correlation coefficients greater than 0.50. The maximum value in the final difference Fourier was  $0.16 \text{ e } \text{\AA}^{-3}$ , and the minimum value  $-0.15 \text{ e } \text{\AA}^{-3}$ . Programs used were *MULTAN82* (Main *et al.*, 1982), *ORTEP* (Johnson, 1965), *PLUTO78* (Motherwell & Clegg, 1978), and *SDP* (Frenz, 1978). Final positional and equivalent isotropic thermal parameters are shown in Table 1, and selected bond lengths, bond angles, and torsion
