four acetate groups. The remaining axial coordination sites on the rhodium ions are coordinated to the N(7) positions of two 1-methyladenosine molecules.

**Experimental.** Crystallized as dark-red plates from a 1:1 methanol/water solution. Enraf-Nonius CAD-4 diffractometer,  $\omega/2\theta$  scan for data collection, lattice parameters from 23 reflections in range  $24 < 2\theta < 85^\circ$ . 8290 measured reflections with index range  $h - 9$  to  $9$ ,  $k - 14$  to  $14$ ,  $l - 14$  to  $14$  up to a  $2\theta_{max}$  of  $154^\circ$ . 4146 unique reflections; 3638 reflections with  $I/\sigma(I) > 2$  used for refinement. Intensities of 145,  $14\bar{5}$ ,  $5\bar{3}\bar{2}$  measured every 2 h; no significant decay

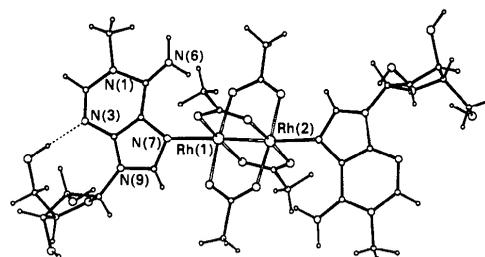

Fig. 1. View of an asymmetric unit of the complex with molecule A on the left side and molecule B on the right side. The coordination bonds are open while the covalent bonds are solid. The intramolecular hydrogen bond is shown as a dashed line.

observed. Empirical absorption correction ( $\varphi$  curve) applied to data; maximum variation of 25%. 4144 reflections measured twice and averaged; discrepancy from the mean is 0.042 defined as  $\sum |F_1 - F_2| / \sum (F_1 + F_2)$ , where  $F_1$  and  $F_2$  are the two observed structure factor magnitudes for each unique intensity.

Structure solved by multisolution technique and non-H atoms refined by full-matrix least squares (on  $F$ ) using anisotropic temperature factors. 26 of 46 H atoms in the asymmetric unit were located from difference Fourier maps but not refined. Some proton positions were adjusted slightly (up to 0.1 Å) to improve bonding geometry, especially for the acetate groups. The remaining 20 H atoms, including all water protons and ribose hydroxyl protons, were fixed based on reasonable geometry to maximize hydrogen-bonding interactions in the crystal lattice.  $R = 0.053$ ,  $wR = 0.072$ ,  $S = 2.49$ ,  $\Delta/\sigma = 0.1$ ,  $w =$

$1/[\sigma^2(F) + (0.02 F_o)^2]$ , residual electron density between  $-2.0$  and  $+1.6 \text{ e } \text{Å}^{-3}$  with the largest residuals in the vicinity of the Rh atoms. Scattering factors for non-H atoms from Cromer & Waber (1965) and for H atoms from Stewart, Davidson & Simpson (1965). Table 1\* gives the atomic parameters. Fig. 1 shows the molecular complex and Table 2 lists the rhodium coordination, nucleoside conformation, and hydrogen-bonding distances. Calculations performed on a MicroVAX II computer using locally developed programs (Rao, Haromy, McAlister & Merritt, unpublished).

**Related literature.** Rhodium(II) carboxylates such as the title compound comprise a series of platinum-group metal complexes which are active anti-cancer agents. These compounds are believed to inhibit tumor cell division by reacting covalently with cellular nucleic acids (Rosenberg, 1978). The crystal structure of a dirhodium tetraacetate tRNA<sup>Phe</sup> complex has also been determined where the dirhodium

tetraacetate forms an intermolecular crosslink between the N(7) atoms of the adenine bases of two symmetry related tRNA molecules (Rubin & Sundaralingam, 1984). The mode of complexation observed in these structures suggests that dirhodium tetraacetate may act by forming interstrand crosslinks to the N(7) positions of two adenine bases in double stranded nucleic acids.

(Reçu le 1 août 1990; accepté le 17 janvier 1990)

**Abstract.** Diammine(5-oxoprolinato)platinum(II), [Pt(C<sub>5</sub>H<sub>5</sub>NO<sub>3</sub>)(NH<sub>3</sub>)<sub>2</sub>],  $M_r = 356.25$ , monoclinic,  $P2_1$ ,  $a = 8.399$  (2),  $b = 7.204$  (2),  $c = 14.508$  (3) Å,  $\beta = 103.64$  (2)°,  $V = 853.1$  (7) Å<sup>3</sup>,  $Z = 4$ ,  $D_x = 2.77 \text{ Mg m}^{-3}$ ,  $\lambda(\text{Mo K}\alpha) = 0.7107$  Å,  $\mu = 16.6 \text{ mm}^{-1}$ ,  $F(000) = 656$ ,  $T = 294$  (1) K,  $R = 0.021$  for 2037 independent observed reflections. The two independent molecules in the asymmetric unit have similar geometries. In both, the Pt atom displays a square-planar *cis* coordination with two N atoms from the NH<sub>3</sub> groups, one N atom and one O atom from the 5-oxoprolinato ligand. The amide function

exhibits the tautomeric iminoalcohol form and loses the proton of the OH group. Formal local charges on the Pt atom and the 5-oxoprolinato ligand are not compensated and the molecule has a zwitterionic character. One of the two NH<sub>3</sub> ligands is involved in an intramolecular hydrogen bond with the O atom of the iminoalcohol group. This structure was solved in order to establish the relationship between the Pt atom and the 5-oxoprolino ligand.

**Partie expérimentale.** Cristal approximativement parallélépipédique:  $0,06 \times 0,10 \times 0,27 \text{ mm}$ . Diffrac-
