#### Abstract

C}_{15} \mathrm{H}_{14} \mathrm{O}_{3}, M_{r}=242.3\), monoclinic, $P c, a=$ 13.219 (1), $\quad b=7.072$ (1), $\quad c=6.527$ (2) $\AA, \quad \beta=$ $97.23(1)^{\circ}, V=605.3(3) \AA^{3}, Z=2, D_{m}$ (flotation) $=$ 1.33 (1), $D_{x}=1.329 \mathrm{Mg} \mathrm{m}^{-3}, \lambda(\mathrm{Cu} K \alpha)=1.5418 \AA$, $\mu(\mathrm{Cu} K \alpha)=0.66 \mathrm{~mm}^{-1}, \quad, \quad F(000)=256, \quad T=$ 291 (1) K, final $R=0.040$ for 905 observed data. The bicyclic molecule adopts a conformation similar to the solid-state conformation of isocolchicine, and the dihedral angle between the planes of the two rings is 41.1 (4) ${ }^{\circ}$.

Introduction. The alkaloid colchicine (1) is a potent antimitotic agent (Brossi, Yeh, Chrzanowska, Wolff, Hamel, Lin, Quin, Suffness \& Silverton, 1988), which exerts its effect by binding to the cytoskeletal protein tubulin. The existence of two partial binding sites on the protein has been established, one for the trimethoxyphenyl $A$ ring and one for the troponoid $C$ ring. In view of this and the potent antimitotic properties of the $A C$-ring analogues (2) (Fitzgerald, 1976) and (3) (Banwell, Herbert, Buckleton, Clark, Rickard, Lin \& Hamel, 1988), comprehensive structure-activity studies of colchicine analogues lacking the central $B$ ring could provide important insights into the mode of the colchicine-tubulin interaction. In addition, such systems might represent potentially useful compounds in a therapeutic sense. As part of a continuing conformational study
of colchicine analogues which might have potential as antimitotic agents (Banwell, Gravatt, Buckleton, Clark \& Rickard, 1989; Banwell, Collis, Crisp, Lambert, Reum, Scoble, Gable, Mackay \& Hamel, 1991), we report here the structure of an $A C$-ring monomethoxyphenyl analogue (4). In earlier studies we reported the structures of the three bicyclic dimethoxyphenyl analogues (5) and (6) (Gable, Mackay, Banwell \& Lambert, 1990) and (7) (Banwell et al., 1991).

(1)

(2) $R=R^{\prime}=R^{\prime \prime}=\mathrm{OCH}_{3}, X=\mathrm{H}$
(3) $R=R^{\prime}=R^{\prime \prime}=\mathrm{OCH}_{3}, X=\mathrm{Cl}$
(4) $R=R^{\prime}=X=\mathrm{H}, R^{\prime \prime}=\mathrm{OCH}_{3}$
(5) $R=R^{\prime}=\mathrm{OCH}_{3}, R^{\prime \prime}=X=\mathrm{H}$
(6) $R^{\prime}=R^{\prime \prime}=\mathrm{OCH}_{3}, R=X=\mathrm{H}$
(7) $R=R^{\prime \prime}=\mathrm{OCH}_{3}, R^{\prime}=X=\mathrm{H}$

Experimental. Pale-yellow prismatic crystals of (4) from benzene, ca $0.24 \times 0.21 \times 0.27 \mathrm{~mm}$, aligned on a Rigaku-AFC diffractometer; cell parameters determined by least-squares from $2 \theta$ values for 25 strong reflections ( $4 \mathrm{I}<2 \theta<78^{\circ}$ ); $\mathrm{Cu} K \alpha$ radiation (graphite crystal monochromator, $\lambda=1.5418 \AA$ ); $\omega-2 \theta$ scan, scan rate $2^{\circ} \mathrm{min}^{-1}$, scan range ( $\Delta \omega$ ) $1.2^{\circ}$ $+0.5^{\circ} \tan \theta, \quad 2 \theta_{\text {max }}=130^{\circ}, \quad 10 \mathrm{~s}$ stationary background counts; three standard reflections monitored every 50 reflections, no significant intensity variation; 1109 unique data, $h 0$ to $15, k 0$ to $8, l-7$ to 7,905 for which $I>2 \sigma(I)$ used for refinement; intensities corrected for Lorentz and polarization effects and for absorption, transmission factors 0.959 to 0.870 . Structure solved by direct methods with SHELXS86 (Sheldrick, 1985) and refined with SHELX76 (Sheldrick, 1976). H-atom sites located by difference, except for those of the methoxy groups, which were included at idealized positions ( $\mathrm{C}-\mathrm{H} 1.08 \AA$ ); no refinement of H -atom coordinates or temperature factors; full-matrix least-squares refinement with anisotropic temperature factors given to C and O atoms, isotropic for H , converged at $R=0.040$ and $w R=0.052, S=1.27$ ( 162 parameters varied); function minimized $\sum w\left(\left|F_{o}\right|-\left|F_{c}\right|\right)^{2}, \quad$ with weights $\left(\sigma^{2}\left|F_{o}\right|+0.0012\left|F_{o}\right|^{2}\right)^{-1}$; one reflection, 020, apparently seriously affected by extinction omitted from the final refinement. At convergence, $(\Delta / \sigma)_{\text {max }}=$ $0.001 ; \quad(\Delta \rho)_{\text {max }}, \quad(\Delta \rho)_{\text {min }}=+0.14, \quad-0.21 \mathrm{e}^{-3} \AA^{-3}$. Atomic scattering factors and anomalous-dispersion factors from International Tables for $X$-ray Crystallography (1974, Vol. IV, pp. 99, 149). Figures were prepared from the output of ORTEPII (Johnson, 1976). Calculations performed on a VAX11/780 computer.

Discussion. Final atomic coordinates for the non-H atoms are given in Table 1,* bond lengths and angles are listed in Table 2 and the molecular conformation and numbering is illustrated in Fig. 1. The molecule (4) adopts a solid-state conformation that resembles isocolchicine (Lessinger \& Margulis, 1978a), an inactive isomer of colchicine, rather than colchicine (Lessinger \& Margulis, 1978b) (1). This solid-state conformation has been adopted without exception by all other bicyclic $A C$-ring analogues so far studied, namely (2) (Rossi, Link \& Lee, 1984), (3) (Banwell et al., 1988), (5) and (6) (Gable et al., 1990), and (7) (Banwell et al., 1991). The tropolone $A$-ring atoms in (4) are coplanar to within 0.04 (1) $\AA$, and

both methoxy groups are coplanar with their associated rings as reflected by the torsion angles $\mathrm{C}(1)$ -$\mathrm{C}(2)-\mathrm{O}(2)-\mathrm{C}\left(2^{\prime \prime}\right)$ of $-177.9(4)^{\circ}$ and $\mathrm{C}\left(3^{\prime}\right)-$ $\mathrm{C}\left(4^{\prime}\right)-\mathrm{O}\left(4^{\prime}\right)-\mathrm{C}\left(4^{\prime \prime}\right)$ of $-3.0(8)^{\circ}$. The dihedral angle between the normals to the two rings in the other bicyclic analogues (see scheme) ranges between 43.4 (3) ${ }^{\circ}$ in (6) and 57.4 (5) ${ }^{\circ}$ in (2).

As only hydrogen-bond acceptors are present in the analogue molecules and the crystals are not solvated, hydrogen-bond formation is precluded. Thus the molecules are held together in the crystal by van der Waals interactions only, with the shortest intermolecular contacts being $\mathrm{C}\left(2^{\prime \prime}\right) \cdots \mathrm{O}\left(4^{\prime}\right)(1+x, y$,

Fig. 1. Perspective view of (4) with thermal ellipsoids scaled to $50 \%$ probability. H atoms are denoted by spheres of arbitrary radius.
z) $3.265(9) \AA$, and $\mathrm{C}\left(2^{\prime \prime}\right) \cdots \mathrm{O}(1)(x, \quad y,-1+z)$ 3.346 (7) $\AA$.
