#### Abstract

Pyrazolyl- $\left.N: N^{\prime}\right)$-bis[( $2,2^{\prime}, 2^{\prime \prime}$-terpyridine)platinum(II)] perchlorate acetonitrile solvate, $\left[\mathrm{Pt}_{2}\left(\mathrm{C}_{15} \mathrm{H}_{11} \mathrm{~N}_{3}\right)_{2}\left(\mathrm{C}_{3} \mathrm{H}_{3} \mathrm{~N}_{2}\right)\right]\left(\mathrm{ClO}_{4}\right)_{3} . \mathrm{CH}_{3} \mathrm{CN}, \quad M_{r}=$ 1263.18, orthorhombic, Pnma, $a=18.172$ (2), $b=$ 17.950 (3), $c=12.086$ (4) $\AA, V=3942.3$ (15) $\AA^{3}, Z=$ $4, D_{x}=2.128 \mathrm{~g} \mathrm{~cm}^{-3}, \lambda($ Mo $K \alpha)=0.71073 \AA, \mu=$ $74.41 \mathrm{~cm}^{-1}, \quad F(000)=2416, \quad$ room temperature ( 297 K ), $R=0.0337$ for 2510 reflections with $F_{o}^{2}>$ $3 \sigma\left(F_{o}^{2}\right)$. A single pyrazolyl unit bridges two Pt centres. The square-planar coordination around each Pt atom is completed by a tridentate terpyridine ligand. The $\mathrm{Pt} \cdots \mathrm{Pt}$ separation is 3.432 (1) $\AA$ with an inclination of 47.7 (12) ${ }^{\circ}$ between the two Pt square planes.

Introduction. We are currently investigating the properties of binuclear terpyridineplatinum(II) complexes. The compound ( $\mu$-pz)bis[ $(\mathrm{tpy}) \mathrm{Pt}]\left(\mathrm{ClO}_{4}\right)_{3}(\mathrm{pz}$ = pyrazolyl, tpy = terpyridine) is one of a series of binuclear complexes that have been synthesized in which the interplatinum distance is varied. The effect of the Pt-atom separation on absorption and emission spectra can be readily studied with these complexes.

Experimental. This material was synthesized by heating an aqueous solution of $[\mathrm{Pt}(\operatorname{tpy}) \mathrm{Cl}] \mathrm{Cl}$ and pyrazole ( $1 / 2$ equiv.) ( pH adjusted to ca 9 with $1 M \mathrm{NaOH}$ ) to 348 K for 5 d . The orange-red solution slowly changed to pale orange. Cooling and addition of $\mathrm{NaClO}_{4}$ precipitated the product as a perchlorate salt. Crystals for X-ray analysis were grown by slow evaporation of an acetonitrile solution. A pale orange tabular block crystal $0.22 \times 0.42$ $\times 0.60 \mathrm{~mm}$ was used for data collection on a CAD-4 diffractometer, with $\omega$-scan technique. 25 reflections with $34<2 \theta<41^{\circ}$ were used for determination of the cell dimensions. An empiricial absorption correction based on $\psi$ scans of six reflections, with relative transmission from 0.508 to 1.388 , was applied. $(\sin \theta / \lambda)_{\max }=0.54 \AA^{-1} ; h$ from -14 to $14, k$ from -21 to $21, l$ from 0 to 17 . Three standard reflections

[^0]$(153,411, \overline{3} 42)$ showed decay of $0.6 \%$ in 148 h of data collection; data were corrected for this decay. 14841 reflections were measured, of which 3588 were independent. Goodness of fit for merging was 1.35 ( $R_{\text {merge }}$ for 378 reflections with exactly two observations, 0.0175 ). All reflections were used in solution and refinement of the structure. Coordinates of the Pt atom were found from a Patterson map, remaining heavy atoms were found by successive structure factor - Fourier calculations, including an acetonitrile molecule of crystallization and two perchlorate ions. $F_{o}^{2}$ magnitudes were used in fullmatrix least-squares refinement, which minimized $\sum w\left(F_{o}^{2}-F_{c}^{2}\right)^{2}$. H atoms were positioned by calculation ( $\mathrm{C}-\mathrm{H}=0.95 \AA$ ) and included as constant contributors to the structure factors. H atoms on the acetonitrile were calculated for two possible positions based on the symmetry of the mirror plane which contains the $\mathrm{CH}_{3} \mathrm{CN}$ molecule; difference and Fourier maps did not favor either conformation so both positions were included, each contributor being set at half occupancy. H -atom parameters were not refined but recalculated once, near the conclusion of the refinement. Positional and anisotropic temperature parameters for all non-H atoms (except O in disordered $\mathrm{ClO}_{4}^{-}$, isotropic), a scale factor and secondary-extinction parameter were refined. At convergence, difference maps suggested that the second $\mathrm{ClO}_{4}^{-}$ion which occupies a special position on a mirror plane might be modeled more appropriately as the superposition of two ions each with half occupancy and sharing both the Cl 2 and O 6 positions. Although this model accounts for most of the electron density in the area and the average $\mathrm{Cl}-\mathrm{O}$ bond length is $1.43 \AA$, the actual bond lengths and angles deviate substantially from a tetrahedral $\mathrm{ClO}_{4}^{-}$ geometry; however, other disorder models did not improve on this result, so refinement was terminated at this stage.
$R=0.0514$ for 3346 reflections with $F_{o}^{2}>0, w R$ (on $F^{2}$ ) $=0.0050$ and goodness of fit $=2.01$ for 3588 reflections and 293 parameters. Weights were taken as $1 / \sigma^{2}\left(F_{o}^{2}\right)$; variances $\left[\sigma^{2}\left(F_{o}^{2}\right)\right.$ ] were derived from counting statistics plus an additional term, $(0.014)^{2}$; variances of the merged data by propagation of error

plus another additional term, $\left(0.014 \overline{)^{2}}\right.$. In the final least-squares cycles $(\Delta / \sigma)_{\max }=0.04 ;-0.91 \leq \Delta \rho \leq$ $1.57 \mathrm{e} \AA^{-3}$ in the final difference Fourier map, with all large peaks within $1.5 \AA$ of the Pt atom. Atomic scattering factores and values for $f^{\prime}$ were taken from Cromer \& Waber (1974) and Cromer (1974). Programs used were those of the CRYM crystallographic computing system (Duchamp, 1964) and ORTEPII (Johnson, 1976). Final atomic coordinates and $U_{\mathrm{eq}}$ are listed in Table 1 with selected distances and angles given in Table 2.*

Discussion. Fig. 1 shows the cation viewed along the intermetal axis with atom labels; Fig. 2 is a stereoscopic view of the entire $3+$ cation. The geometry around the Pt atoms is nearly square planar, distorted only by the restricted bite angle of the planar

[^1]Fig. 1. A labeled $O R T E P$ II (Johnson, 1976) drawing of the cation with $50 \%$ probability ellipsoids viewed down the intermetal axis. H atoms are not shown.

Fig. 2. An ORTEPII (Johnson, 1976) stereoscopic drawing showing the complete cation. Atoms are shown as $50 \%$ probability ellipsoids.
terpyridine unit. This results in a short $\mathrm{Pt}-\mathrm{N} 3$ distance [1.938 (5) $\AA$ ] and an $\mathrm{N} 2-\mathrm{Pt}-\mathrm{N} 4$ trans bond angle of only 162.2 (2) ${ }^{\circ}$. The remaining bond lengths around the Pt atom are all over $2 \AA$ [2.018 (6), 2.020 (5) and 2.031 (6) $\AA$ ]. This geometry is entirely consistent with other related $\mathrm{Pt}(\mathrm{tpy})$ complexes (Dewan, Lippard \& Bauer, 1980; Ratilla, Scott, Moxness \& Kostic, 1990; Wong \& Lippard, 1977; Jennette, Gill, Sadownick \& Lippard, 1976).

The two Pt atoms are bridged by a single pyrazolyl group, resulting in a $\mathrm{Pt} \cdots \mathrm{Pt}$ separation of 3.432 (1) $\AA$ (parallel, by symmetry, with the $y$ axis) and an inclination between the two square planes of 47.7 (12) ${ }^{\circ}$. This distance is intermediate in the range of $\mathrm{Pt}^{\mathrm{II}} \ldots \mathrm{Pt}^{\mathrm{II}}$ separations exhibited by other binuclear tpy complexes, that have been observed as short as $2.9884 \AA$ (Ratilla et al., 1990) and as long as $4.420 \AA$ (Dewan et al., 1980). The Pt atom is displaced out of the terpyridine plane by ca $0.2 \AA$ towards the other Pt atom in the same binuclear unit. The bond lengths and angles within each pyridine ring are characteristic of a delocalized aromatic system, ranging from 1.334 (10) to $1.395(14) \AA$ and from 117.2 (8) to 124.9 (7) ${ }^{\circ}$. Similarly, the bond lengths and angles within the pyrazolyl ring range from 1.331 (13) to 1.340 (9) $\AA$ and from 105.1 (9) to 110.5 (8) ${ }^{\circ}$, thereby
demonstrating the delocalized nature of the $\pi$ electrons in the five-membered ring.

We thank Larry Henling for his assistance. This work was supported by an NSERC (Canada) Postdoctoral Fellowship to JAB and a grant from the Office of Naval Research (N00014-89-J-3198).
