occupies a special position on a twofold axis; $\mathrm{K}(2)$ is at a general position. Both types of K atoms are surrounded by ten O atoms. The $\mathrm{K}-\mathrm{O}$ distances in each coordination polyhedron are shown by dotted lines in Fig. 1. The $\mathrm{K}-\mathrm{O}$ distances in each $\mathrm{KO}_{10}$ polyhedron in TKHSe are more scattered than those in TRHSe and TRDSe.

The two $\mathrm{SeO}_{4}$ groups in the dimer are related by a centre of symmetry, at which the H atom is located or positionally disordered. The large $B$ value of the H atom appears to favour the disordering (Table 2). The dimensions and systematic trends in distortion from a regular tetrahedron of the $\mathrm{SeO}_{4}$ anion, as shown from the bond lengths and angles, are close to those in TRHSe and TRDSe [for detailed discussion consult Ichikawa et al. (1992a)]. Furthermore, a trend among the values of the equivalent isotropic displacement parameters and the disk-like anisotropy in the $\mathrm{O}(2)(\mathrm{H})$ and $\mathrm{O}(3)$ atoms are similarly observed in the Rb and Cs analogues [see the deposited list of anisotropic displacement parameters and Ichikawa, Gustafsson \& Olovsson (1992b)].
The hydrogen-bond distance $\mathrm{O}(2) \cdots \mathrm{O}\left(2^{\mathrm{ii}}\right)$ is 2.524 (5) $\AA$. This value is the shortest among the members of the $M_{3} \mathrm{H}\left(\mathrm{SeO}_{4}\right)_{2}$ family exhibiting a lowtemperature phase transition. That also means that $\mathrm{K}_{3} \mathrm{H}\left(\mathrm{SeO}_{4}\right)_{2}$ with the shortest hydrogen bond has the lowest transition temperature. We thus expect that a linear relation between the transition temperature and hydrogen-bond distance at $T_{c}$ is also valid for the $M_{3} \mathrm{H}\left(\mathrm{SeO}_{4}\right)_{2}$ family (Ichikawa, Motida \& Yamada, 1987). Structure analysis at 30 K is now in progress, which will give us the definite conclusion to the validity of the linear correlation.

Data collection was performed using facilities of the Institute for Solid State Physics, the University of Tokyo. All calculations were carried out at the Institute of Chemistry, Uppsala University. One of the authors (MI) wishes to thank Professor Ivar Olovsson for placing courteously at his disposal the computer and programs, and for reading the manuscript, and Dr Torbjörn Gustafsson for his help during calculation and preparation of the manuscript. The work was partly supported by a Grant-in-Aid for Cooperative Research (02302021) from the Ministry of Education, Science and Culture, Japan.

# A Neutron Powder Diffraction Study of $\mathrm{HIO}_{3}$ and $\mathrm{DIO}_{3}$ 

By Kenny Ståhl<br>Inorganic Chemistry 2, University of Lund, POB 124, S-221 00 Lund, Sweden<br>and Marek Szafranski<br>Institute of Physics, Adam Mickiewicz University, Grunwaldzka 6, P-60-780 Poznań, Poland

(Received 27 November 1991; accepted 22 January 1992)

Abstract. The crystal structures of hydrogen iodate, $\mathrm{HIO}_{3}$, and its deuterated form, $\mathrm{DIO}_{3}$, have been refined using the Rietveld method from neutron powder-diffraction data; $\lambda=1.470$ (1) $\AA, T=295 \mathrm{~K}$, $P 2_{1} 2_{1} 2_{1}, Z=4 ; \mathrm{HIO}_{3}: M_{r}=175.91, a=5.5448$ (3), $b$

$$

5.8745 (4), $c=7.7356$ (5) $\AA, V=251.79(5) \AA^{3}, D_{x}=$ $4.67 \mathrm{~g} \mathrm{~cm}^{-3}, \mu=0.06 \mathrm{~cm}^{-1}, 10 \leq 2 \theta \leq 128^{\circ}$ in 1475 steps, $R_{p}=4.64 \%, R_{w p}=6.17 \%, \mathrm{GOF}=5.92, R_{F}=$ $1.50 \%$ (307 Bragg reflections) and 37 refined parameters. The iodate group forms a pyramid with I as one apex. H/D forms rather linear $\mathrm{O}-\mathrm{H} / \mathrm{D} \cdots \mathrm{O}$ hydrogen bonds with $\mathrm{O}-\mathrm{H} 0.968$ (9) and $\mathrm{O}-\mathrm{D}$ 1.009 (7) $\AA$. With the inclusion of next-nearest neighbours at distances 2.5 to $3.5 \AA$, the I-O coordination can be described as a capped trigonal prism, with I approximately on the capped face of the prism. The $\mathrm{H} / \mathrm{DIO}_{3}$ structures are of the anticementite type, with H/D in one face of the octahedral interstices (empty in cementite) and with the I-atom lone pair approximately at the centre of the prisms (the cementite C position).

Introduction. The crystal structure of $\mathrm{HIO}_{3}$ has previously been determined by Rogers \& Helmholz (1941) (X-rays) and Garret (1954) (neutrons, 0 kl and $h 0 l$ zones, Fourier refinement). Modelling of the optical and spectroscopic properties of $\mathrm{HIO}_{3}$ and $\mathrm{DIO}_{3}$ (Szafranski, 1991) raised the need for more accurate structural data. The present study is an attempt to obtain this from neutron powderdiffraction data. It is the first least-squares refinement of the $\mathrm{HIO}_{3}$ structure and the first structural study of $\mathrm{DIO}_{3}$ reported.

Experimental. The $\mathrm{HIO}_{3}$ sample used was commercially available AnalaR quality, BDH Chemicals Ltd, Poole, England. $\mathrm{DIO}_{3}$ was obtained from five-times-repeated recrystallizations through slow evaporation at 323 K from $\mathrm{D}_{2} \mathrm{O}$ with addition of $\mathrm{DNO}_{3}$, starting with $\mathrm{HIO}_{3}$. The samples were ground and packed through vibrations in an ultrasonic bath in a vanadium sample container of 11 mm diameter and 50 mm height. Both data sets were collected at the powder diffraction beam line at The Studsvik Neutron Research Laboratory, Sweden. The wavelength, 1.470 (1) $\AA$, was obtained using a $\mathrm{Cu}(220)$ double-crystal monochromator, calibrated with $\mathrm{Al}_{2} \mathrm{O}_{3}$. The diffractometer is built on a Huber $\omega / 2 \theta$ goniometer, operating in parallel mode, equipped with an array of ten ${ }^{3} \mathrm{He}$ detectors, $3.12^{\circ}$ apart, and with $10^{\prime}$ Soller slits in front. The data sets were collected at ambient pressure and temperature in $2 \theta$ step sizes of $0.08^{\circ}$, each step measured for approximately 2 min (monitor controlled) without sample rotation.

The Rietveld analysis program used in this study is essentially the LHMP1 program described by Hill \& Howard (1986) modified to fit the local I/O formats. The program minimizes the quantity $\sum w_{i}\left(Y_{i o}-Y_{i c}\right)^{2}$ with $w_{i}=1 / Y_{i o}$. Pseudo-Voigt functions were used in both refinements with a Lorentzian component $\gamma=$ $\gamma_{1}+\gamma_{2} 2 \theta$, where $\gamma_{1}\left(\mathrm{HIO}_{3}\right.$ and $\left.\mathrm{DIO}_{3}\right)$ and $\gamma_{2}\left(\mathrm{DIO}_{3}\right)$
were refined. The FWHM is defined as $\left(U \tan ^{2} \theta+\right.$ $V \tan \theta+W)^{1 / 2}$, where $U, V$ and $W$ were refined using a peak width of five half widths. The $2 \theta$ zero point and six background parameters $\left[B_{i}=\sum B_{i m}(2 \theta)^{m}, m\right.$ $=-1,0,1,2,3,4]$ were refined as well as one asymmetry parameter for $2 \theta \leq 30^{\circ}\left(\mathrm{HIO}_{3}\right)$ and one preferred-orientation parameter $\left(\mathrm{DIO}_{3}\right)$. The data sets were corrected for absorption according to Rouse, Cooper, York \& Chakera (1970), giving maximum corrections of $1.40\left(\mathrm{HIO}_{3}\right)$ and 1.04 $\left(\mathrm{DIO}_{3}\right)$. One overall scale factor, three unit-cell parameters and fractional coordinates and isotropic temperature factor coefficients of all atoms were refined for both data sets. The refinements were started with parameters from Garret (1954). Neutron scattering lengths were taken from Koester, Rauch, Herkens \& Schroeder (1981). The maximum shift/ e.s.d. in the final cycle was less than 0.1 in both refinements. On introduction of anisotropic temperature factor coefficients the refinements converged to $R_{w p}=1.82 \%$ and $5.52 \%$ for $\mathrm{HIO}_{3}$ and $\mathrm{DIO}_{3}$ respectively. The anisotropic model, with 25 more parameters, cannot be rejected on the 0.005 level according to the Hamilton $R$-value test (International Tables for $X$-ray Crystallography, 1974, Vol. IV). However, as most of the temperature factors did not become positive definite and e.s.d.'s generally increased, the isotropic model was retained.
$R$ values used are defined as $R_{p}=\sum \mid Y_{i o}-$ $Y_{i c} / / \sum Y_{i o}, \quad R_{w p}=\left[\sum w_{i}\left(Y_{i o}-Y_{i c}\right)^{2}\right]\left[\sum w_{i} Y_{i o}^{2}\right]^{1 / 2}, \quad$ GOF $=\sum w_{i}\left(Y_{i o}-Y_{i c}\right)^{2} /(N-P)$ and the derived Bragg $R$ values, $\quad R_{I}=\sum\left|I_{k o}-I_{k c}\right| / \sum I_{k o}, \quad R_{F}=\sum \mid F_{k o}-$ $F_{k c} / \sum F_{k o}$. Additional information on data collections and refinements is given in Table 1, and the final fractional coordinates and isotropic mean values of the temperature factor coefficients are given in Table 2. The powder diffraction patterns with their final difference patterns are shown in Fig. 1.*

Discussion. The geometric details of the $\mathrm{HIO}_{3}$ and $\mathrm{DIO}_{3}$ structures are given in Table 3 and compared to those found by Garret (1954). The iodate ion forms a pyramid with the I-atom lone pair pointing at the fourth vertex of a tetrahedron. With inclusion of next-nearest neighbours at distances $2.50-3.50 \AA$, the I-O coordination can be described as a distorted capped trigonal prism, with the I atom approximately on the capped prism face. The $\mathrm{HIO}_{3}$ and $\mathrm{DIO}_{3}$ structures are of the anti-cementite type (Hyde \& Andersson, 1989), related to the $\mathrm{NaIO}_{3}$

also reflected in the larger $\mathrm{HIO}_{3}$ unit cell. The present results on $\mathrm{HIO}_{3}$ are in agreement with those found by Garret (1954), but at an apparent higher level of precision. However, e.s.d.'s and significance of small differences between results obtained in this study, using the Rietveld method, and those of Garret (1954), using Fourier refinements, have to be treated cautiously owing to the likely underestimate of the e.s.d's by the two methods. In order to further increase the precision in the structure determinations of $\mathrm{HIO}_{3}$ and $\mathrm{DIO}_{3}$, single-crystal neutron diffraction studies will be attempted in the near future.

Technical assistance by Mr Håkan Rundlöf, Studsvik, and financial support from the Swedish Natural Science Research Council, is gratefully acknowledged.

# Structure of Pentaamminechlororuthenium(III) Bisulfate Tetrahydrate 

By Elizabeth John, Harvey J. Schugar and Joseph A. Potenza<br>Department of Chemistry, Rutgers, The State University of New Jersey, New Brunswick, New Jersey 08903, USA

## (Received 5 August 1991; accepted 31 January 1992)

#### Abstract

RuCl}\left(\mathrm{NH}_{3}\right)_{5}\right]\left(\mathrm{HSO}_{4}\right)_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}, M_{r}=487.88\), triclinic, $P \overline{1}, a=10.0422$ (5),$b=14.1044$ (7), $c=$ 6.3273 (6) $\AA, \alpha=100.369$ (5), $\beta=98.655$ (6), $\quad \gamma=$ 81.354 (4) ${ }^{\circ}, V=864.5$ (3) $\AA^{3}, Z=2, \quad D_{m}=1.86$ (1), $D_{x}=1.874 \mathrm{~g} \mathrm{~cm}^{-3}, \quad \lambda($ Мо $K \alpha)=0.71073 \AA, \quad \mu=$ $13.3 \mathrm{~cm}^{-1}, \quad F(000)=498, \quad T=296(1) \mathrm{K}, \quad R=0.025$ for 4622 unique reflections with $I>3 \sigma(I)$. The structure contains $\left(\mathrm{NH}_{3}\right)_{5} \mathrm{RuCl}^{2+}$ cations, bisulfate anions and solvate water molecules all linked by an extensive hydrogen-bonding network. Each Ru ion is coordinated in a distorted octahedral fashion by five ammonia molecules and a chloride ion. The $\mathrm{Ru}-\mathrm{Cl}$ distance $\left[2.3742(5) \AA\right.$ ] is typical for $\mathrm{Ru}^{\mathrm{II}}-\mathrm{Cl}$ linkages. The $\mathrm{Ru}-\mathrm{NH}_{3}$ distances span a narrow range [2.096 (2)-2.119 (2) $\AA$ ] and provide no evidence for a trans effect.

Introduction. For some time we have been interested in the ligand to metal charge-transfer spectra of pentaammineruthenium(III) $L$ complexes, where $L=$ thioether (Krogh-Jespersen, Zhang, Westbrook, Fikar, Nayak, Kwik, Potenza \& Schugar, 1989) or imidazole (Krogh-Jespersen, Westbrook, Potenza \& Schugar, 1987). Such complexes are prepared by reaction of $\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Ru}^{\mathrm{II}} \mathrm{H}_{2} \mathrm{O}$ with an excess of the appropriate ligand, followed by air oxidation to the
$\mathrm{Ru}^{\text {III }}$ state. This intermediate in turn is prepared by the reduction of $\left[\left(\mathrm{NH}_{3}\right)_{5} \mathrm{RuCl}\right]^{2+}$ with zinc amalgam which is accompanied by rapid aquation of the initial $\left[\left(\mathrm{NH}_{3}\right)_{5} \mathrm{RuCl}\right]^{+}$product. In an attempt to prepare the sulfate salt of $\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Ru}^{\mathrm{II}} L$, where $L=2$, 4,6-trihydroxybenzoate, by a variation of a published procedure (Stritar \& Taube, 1969), the addition of saturated aqueous $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}$ to an acidic solution which contained some unreacted $\left[\left(\mathrm{NH}_{3}\right)_{5} \mathrm{RuCl}\right]^{2+}$ precipitated this cation as its bisulfate salt. We report here the structure of this cation. A limited ( $R_{F}=$ 0.169 , visually estimated intensities) early crystallographic study of the chloride analogue $\left[\left(\mathrm{NH}_{3}\right)_{5}\right.$ $\mathrm{RuCl}^{2} \mathrm{Cl}_{2}$ has been reported (Prout \& Powell, 1962).

Experimental. The acidic reaction mixture noted above was layered over a saturated $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}$ solution in a test tube. After a week at room temperature, well formed rectangular plates showing a yellow, dark-yellow dichroism deposited. $D_{m}$ was measured by flotation.

A yellow plate $0.15 \times 0.30 \times 0.32 \mathrm{~mm}$ crystal was mounted in a capillary and data collected using an Enraf-Nonius CAD-4 diffractometer with graphitemonochromated Mo $K \alpha$ radiation and $\theta-2 \theta$ scans. No systematic absences were observed. Cell con-
