$90 \% d$ and $l$ isomers it is possible that some of the isomers converted to the meso isomer between the preparation of the solution and the EXAFS measurement. Since these isomers exist in equilibrium in solution and both racemic and meso forms crystalize from the same solution, care must be taken in analyzing and interpreting results using techniques such as EXAFS where bulk samples are used.

This research was carried out at Brookhaven National Laboratory under contract DE-AC0276 CH 00016 with the US Department of Energy and supported by its Division of Chemical Sciences, Office of Basic Energy Sciences.

# Structure of a Permethylcyclopentadienyl- $\mu$-tetramethylcyclopentadienylmethylene Scandium Dimer 

By Sharad Hajela, William P. Schaefer and John E. Bercaw<br>Division of Chemistry and Chemical Engineering $\dagger$ and The Beckman Institute, Mail Code 139-74, California Institute of Technology, Pasadena, California 91125, USA

(Received 26 December 1991; accepted 11 February 1992)

#### Abstract

Bis}\left(\eta^{5}\right.\)-pentamethylcyclopentadienyl)-bis $[\mu$ -2,3,4,5-tetramethyl-1-methylene-Sc $C^{1}: \mathrm{Sc}^{\prime}\left(\eta^{5}\right)$-cyclo-pentadienyl]-discandium(III), [ $\mathrm{Sc}_{2}\left(\mathrm{C}_{10} \mathrm{H}_{15}\right)_{2^{-}}$ $\left.\left(\mathrm{C}_{10} \mathrm{H}_{14}\right)_{2}\right], M_{r}=628.90$, triclinic, $P \overline{1}, a=8.641$ (5), $b$ $=9.478(2), \quad c=12.338(5) \AA, \quad \alpha=75.58(3), \quad \beta=$ 80.39 (4),$\gamma=63.75$ (3) ${ }^{\circ}, V=875.8$ (7) $\AA^{3}, Z=1, D_{x}$ $=1.19 \mathrm{~g} \mathrm{~cm}^{-3}, \quad \lambda($ Mo K $\alpha$ ) $=0.71073 \AA, \quad \mu=$ $4.11 \mathrm{~cm}^{-1}, F(000)=340$, room temperature, $R$ (on $F)=0.046$ for 2241 reflections with $F_{o}^{2}>3 \sigma\left(F_{o}^{2}\right)$. Two bis(pentamethylcyclopentadienyl)scandium molecules are joined across a center of symmetry. One of the $\mathrm{Cp}^{*}$ methyl groups has lost an H atom and that methylene group bonds to the symmetry-related Sc atom: Sc-C6' $=2.282(5) \AA$. Other aspects of the bis-Cp*Sc geometry are normal.

Introduction. Alkyl and hydride derivatives of permethylscandocene are of interest both for their $\mathrm{C}-\mathrm{H}$ bond-activation chemistry (Thompson, Baxter, Bulls, Burger, Nolan, Santarsiero, Schaefer \& Bercaw, 1987) and as model systems for Ziegler-Natta catalysis (Burger, Thompson, Cotter \& Bercaw, 1990). A notable feature of these complexes is their ability to activate the primary $\mathrm{C}-\mathrm{H}$ bonds of mol-

[^0]0108-2701/92/101771-03\$06.00
ecules such as $\mathrm{CH}_{4}, \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{3}, \mathrm{Si}\left(\mathrm{CH}_{3}\right)_{4}$ and $\mathrm{P}\left(\mathrm{CH}_{3}\right)_{3}$ (Thompson et al., 1987). During the course of some recent mechanistic studies, we have observed that the cyclopentylmethyl derivative, $\mathrm{Cp}_{2}^{*} \mathrm{ScCH}_{2}{ }^{-}$ (cyclo- $\mathrm{C}_{5} \mathrm{H}_{8}$ ) $\quad\left[\mathrm{Cp}^{*}=\boldsymbol{\eta}^{5}-\mathrm{C}_{5}\left(\mathrm{CH}_{3}\right)_{5}\right]$, slowly and cleanly decomposes in cyclohexane to give methylcyclopentane and a yellow crystalline precipitate. The ${ }^{1} \mathrm{H}$ NMR spectrum of the yellow product is consistent with a compound containing one $\mathrm{Cp}^{*}$ and one $\left(\eta^{5}, \boldsymbol{\eta}^{1}\right)-\mathrm{C}_{5}\left(\mathrm{CH}_{3}\right)_{4} \mathrm{CH}_{2}$, the latter arising via metallation of a $\mathrm{Cp}^{*}$ ligand (i.e. a 'tuck-in' complex). This same tuck-in complex has been previously obtained from thermolysis of $\mathrm{Cp}_{2}^{*} \mathrm{ScCH}_{3}$ (Thompson et al., 1987); however, the solid product obtained previously was not crystalline and was postulated to be oligomeric based on its solubility properties. We report herein the structure of the complex which crystallizes as the dimer, $\left[\operatorname{Cp}{ }^{*} \operatorname{Sc}\left\{\mu-\left(\boldsymbol{\eta}^{5}, \eta^{\mathrm{l}}\right)\right.\right.$ $\left.\left.\mathrm{C}_{5}\left(\mathrm{CH}_{3}\right)_{4} \mathrm{CH}_{2}\right\}\right]_{2}$, when allowed to form slowly at room temperature.

Experimental. A parallelepiped, $0.4 \times 0.2 \times 0.05 \mathrm{~mm}$, crystal was used for data collection on a CAD-4 diffractometer with $\omega$ scans. 25 reflections with $24<$ $2 \theta<28^{\circ}$ were used for determination of the unit cell. No absorption correction was applied to the data

collection; $(\sin \theta / \lambda)_{\max }=0.59 \AA^{-1} ; h$ from -10 to 10 , $k$ from -11 to $11, l$ from -14 to 14 . Three standard reflections ( $300,023,030$ ) showed no variations greater than expected from counting statistics. 6239 reflections were measured, of which 3068 were independent; goodness of fit for merging was 0.98 ; $R_{\text {int }}$ for 2682 reflections with exactly two observations was 0.032 . All reflections were used in solution and refinement of the structure. The Sc -atom position was determined from a Patterson map and the C atoms were all found in a subsequent Fourier map. H atoms were placed at idealized positions based on difference maps calculated in their expected planes ( $\mathrm{C}-\mathrm{H}=0.95 \AA$ ). H atoms on C 6 were found in a three-dimensional difference map and their positions and isotropic displacement parameters were refined, but all other H -atom parameters were fixed. Positional and anisotropic displacement parameters of the Sc and C atoms, plus the C 6 H -atom parameters and a scale factor were refined. For all 2856 reflections with $F_{o}^{2}>0, R($ on $F)=0.062, w R\left(\right.$ on $\left.F^{2}\right)=$ $0.010, S=2.19$ for 3068 reflections and 198 parameters. Weights were calculated as $1 / \sigma^{2}\left(F_{o}^{2}\right)$; variances [ $\left.\sigma^{2}\left(F_{o}^{2}\right)\right]$ were derived from counting statistics plus an additional term, $(0.014 I)^{2}$; variances of the merged
data by propagation of e.s.d. plus another additional term, $(0.014 \bar{\eta})^{2}$. Maximum shift/e.s.d. in the final cycle was 0.02 . Maximum and minimum heights in final difference Fourier map were 0.40 and $-0.35 \mathrm{e} \AA^{-3}$, respectively. Atomic scattering factors were obtained from Cromer \& Waber (1974), and the dispersion correction for Sc from Cromer (1974). Computer programs used were those of the CRYM crystallographic computing system (Duchamp, 1964) and ORTEP (Johnson, 1976). Final refined parameters of the atoms are given in Table 1* with selected distances and angles in Table 2. Fig. 1 shows a

labeled drawing of the dimer; crystal packing is shown in Fig. 2.

Discussion. The dimer is joined across an inversion center by an $\left(\eta^{5}, \eta^{1}\right)$-Cp* group which bridges the two symmetry-related Sc atoms. The $\eta^{1}$-methylene (C6) has been formed as the result of $\mathrm{C}-\mathrm{H}$ activation of a $\mathrm{Cp}^{*}$ methyl group. A somewhat surprising result is that, in all other regards, the bonding is very similar to that determined for $\mathrm{Cp}_{2}^{*} \mathrm{ScCH}_{3}$ (Thompson et al., 1987). The ( $\eta^{5}, \eta^{1}$ )-ring remains planar with a maximum deviation of only $0.22 \AA$ from the least-squares plane calculated for C 1 through C10. The geometry about C6 is essentially tetrahedral; the angles $\mathrm{C} 1-\mathrm{C} 6-\mathrm{Sc}^{\prime}, \mathrm{C} 1-\mathrm{C} 6-\mathrm{H} 6 A$, $\mathrm{C} 1-\mathrm{C} 6-\mathrm{H} 6 B$ and $\mathrm{H} 6 A-\mathrm{C} 6-\mathrm{H} 6 B$ are 118.9, 107.3, 104.8 and $98.1^{\circ}$, respectively, giving an average value of 107.3 (8.6) ${ }^{\circ}$. The $\mathrm{H} 6 A-\mathrm{C} 6-\mathrm{H} 6 B$ angle is slightly compressed $\left(98.1^{\circ}\right)$ while the $\mathrm{C} 1-\mathrm{C} 6-\mathrm{Sc}^{\prime}$ angle is somewhat opened ( $118.9^{\circ}$ ). The $\mathrm{Sc}^{\prime} \cdots \mathrm{H} 6 \mathrm{~A}$ and $\mathrm{Sc}^{\prime} \cdots \mathrm{H} 6 B$ distances are 2.76 (3) and 2.79 (3) $\AA$ indicating that there is no agostic interaction for the $\alpha-\mathrm{H}$ atoms with the Sc center. The $\mathrm{Cp}^{*}-\mathrm{Sc}-\mathrm{Cp}^{*}$ angle ( $141.8^{\circ}$ ) is approximately the same as for $\mathrm{Cp}_{2}^{*}$
$\mathrm{ScCH}_{3}\left(144.7^{\circ}\right)$ suggesting that formal replacement of a methyl ligand with a bulkier $\left(\eta^{5}, \eta^{1}\right)-\mathrm{Cp}^{*}$ group as the alkyl does not significantly perturb the Sc- $\mathrm{Cp}^{*}$ bonding.

#### Abstract

Bis(tetrahydrofuran)lithium [bis(2-trimethylsilyl-4-tert-butyl- $\eta^{5}$-cyclopentadienyl)dimethylsilane]dichloroyttrate, $\left[\mathrm{Li}\left(\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\right)_{2}\right]\left[\mathrm{Y}\left(\mathrm{C}_{26} \mathrm{H}_{48^{-}}\right.\right.$ $\left.\mathrm{Si}_{3}\right) \mathrm{Cl}_{2}$ ], $M_{r}=755.87$, triclinic, $P \overline{1}, a=13.110$ (8), $b$ $=17.163$ (15), $c=20.623$ (14) $\AA, \alpha=104.02$ (7), $\beta=$ $99.38(5), \quad \gamma=100.24(6)^{\circ}, \quad V=4326$ (6) $\AA^{3}, \quad Z=4$, $D_{x}=1.16 \mathrm{~g} \mathrm{~cm}^{-3}, \quad \lambda($ Mo K $\alpha)=0.71073 \AA, \quad \mu=$ $15.86 \mathrm{~cm}^{-1}, F(000)=1608$, room temperature, $R=$ 0.056 for 6136 reflections with $F_{o}^{2}>3 \sigma\left(F_{o}^{2}\right)$. There are two virtually identical molecules in the asymmetric unit. In each, the Y atom is tetrahedrally coordinated to a substituted Si-bridged bis(cyclopentadienyl) ligand and to two Cl ions in the cleft. The Li atom is $2.35 \AA$ from each Cl ion, and two molecules of tetrahydrofuran are connected to the Li , completing its tetrahedral coordination.

[^1]Introduction. The Ziegler-Natta polymerization of olefins has occupied the attention of chemists for nearly four decades. Recently, the development of homogeneous transition-metal catalyst systems has afforded the possibility of mechanistic investigations into various key steps of polymer initiation, propagation and chain termination. Brintzinger and coworkers have developed a series of ansa-zirconocene catalysts which possess a $C_{2}$ symmetric ligand arrangement about the metal center (Roll, Brintzinger, Rieger \& Zolk, 1990; Wiesenfeldt, Reinmuth, Barsties, Evertz \& Brintzinger, 1989). Moreover, activation of these ansa-zirconocene catalysts with methylalumoxane results in production of highly isospecific polymers. Work in this laboratory has centered on the study of well defined singlecomponent Ziegler-Natta-type catalyst systems (Piers, Shapiro, Bunel \& Bercaw, 1990). We report
