**Abstract**

Steric repulsion of the bulky Cl atoms causes the perchlorophenyl rings to rotate out of the plane of the central double bond eliminating the conjugation between the three  $\pi$  systems. Molecules pack as interlocking dimers and the dimeric pairs adhere by face-to-face  $\pi$  stacking.

**Comment**

Sterically congested stilbenes (Gano, Park, Subramaniam, Lenoir & Gleiter, 1991; Gano, Park, Pinkerton & Lenoir 1990, 1991; Gano, Subramaniam & Birnbaum, 1990) and the effect that steric congestion has on (Z)/(E)-isomerization barriers (Gano, Lenoir, Park & Roesner, 1987) have been of some interest to us. Our attention was drawn to the very high isomerization barrier reported for (Z)-perchlorostilbene (Ballester & Rosa, 1960), a member of the large class of known perchloroarenes (Ballester, 1989). Alternative explanations for the observed results based on our earlier work prompted an X-ray structural determination of this molecule to verify the structure and reveal the geometry. The original structural assignment for (Z)-perchlorostilbene is confirmed and a highly twisted geometry is demonstrated.

The structure of (Z)-perchlorostilbene was calculated using force-field programs (*PCModel* with and without the *PI* option; Gilbert & Gyjewski, 1992) and semi-empirical programs (*MOPAC* with the *AM1* and *PM3* parameter sets; Dewar, Zoebisch, Healy & Stewart, 1985; Stewart, 1989). All programs gave the same general structure. The force-field calculation which included a *PI* contribution, *MMX(PI)*, gave the best fit and showed no major faults in its structure. The simple force-field program *MMX* greatly underestimated the out-of-plane twisting of the phenyl groups. This failure reoccurs with twisted  $\pi$  systems using this approach. Surprisingly, the semi-empirical programs fail to predict the twist about the central double bond.

The structure of (Z)-perchlorostilbene is shown in Fig. 1 and some selected structural features are noted in Table 3. The central double bond is twisted 6.4 (3)°, based on the Cl atoms, or –11.5 (5)° based on the phenyl groups. The phenyl rings are rotated out of the plane of the double bond by, on average, 76° each, preventing the strong conjugation of the three  $\pi$  systems, as would have occurred had the system been planar. The bond length  $C_{sp^2}=C_{sp^2}$  of 1.336 (3) Å is typical for the  $C=C-C_{ar}$  system (1.339 Å; Allen, Kennard, Watson, Brammer, Orpen & Taylor, 1987), but the average value of the single bond, 1.484 (3) Å, is closer to that observed in *o*-biphenyls (1.487 Å) than in the conjugated  $C=C-C_{ar}$  system (1.470 Å; Allen *et al.* 1987). The slightly shortened  $C_{sp^2}-Cl$  bonds of average length 1.727 (2) Å, compared with 1.734 Å (Allen *et al.*, 1987), indicates the involvement of the vicinal Cl atoms in the electronic interactions and support its similarity to *o*-biphenyls. A similar arrangement of the pentachlorophenyl rings has been observed in perchloro-1,2,3-triphenylnaphthalene (Gali, Solans, Miravittles, Font-Altaba & Armet, 1978), where the perchlorophenyls are rotated out of the plane defined by the  $C-C-C$  fragment of the naphthalene ring by an average of 73°. The twist of the aromatic rings allows the molecule to adopt a 'staggered' rather than 'eclipsed' conformation (see the Newman

projection, Fig. 1*b*) as is observed in the overcrowded sandwich-type molecules like ferrocenes and ferrocenophanes (Kaluski & Skrzypczak-Jankun, 1978), where the distance and dihedral angle between the aromatic moieties is much smaller. In this case, the three-dimensional arrangement of the molecules in the crystal seems to be an important factor.

Fig. 1. (a) Front view of (*Z*)-perchlorostilbene showing atom labeling and 50% probability thermal ellipsoids. (b) Newman projection of (*Z*)-perchlorostilbene viewed along the central double bond.

The packing diagram for (*Z*)-perchlorostilbene is shown in Fig. 2. The (*Z*)-perchlorostilbene units appear as pairs fitting together at opposing phenyl rings like two interlocked clamshells. These pairs are then associated with one another through a face-to-face  $\pi$  stacking interaction. The  $\chi^2$  values associated with the mean least-squares planes calculated for the phenyl rings are 44 for C(2)–C(7) and 235 for C(9)–C(14), showing that the aromatic rings are not strictly planar. The planarity of the phenyl ring C(9)–C(14) engaged in the face-to-face interaction is more disturbed than for the C(2)–C(7) ring that is close to its symmetry mate and also involved in the face-to-edge interaction with the C(9)–C(14) pentachlorophenyl of another molecule. The distances between the planes of the parallel C(9)–C(14) and C(2)–C(7) pairs are 3.7 and 3.3 Å, respectively. The shortest intermolecular contact in the face-to-face interaction is Cl(4)··Cl(7) at 3.365 (1) Å; the shortest contact in the face-to-edge interaction is Cl(12)··C(5) at 3.384 (2) Å. Face-to-face and face-to-edge orientations of aromatic fragments are frequently observed in proteins, as a stabilizing factor in

their tertiary structure. The Cl substituents are significantly out of the plane of the phenyl ring with Cl(7) and Cl(4) being most affected. The mean  $C_{ar}$ –Cl distance of 1.716 (5) Å agrees well with the value of 1.722 Å calculated for 81 such bonds in the other pentachlorophenyls (Miratvilles, Molins, Solans, Germain & Declercq, 1985; Pedersen, 1975; Veciana, Carilla, Miratvilles & Molina, 1987; Armet *et al.*, 1987; Wang, Chen, Xu, Zhang, Pan & Tang, 1987; Gali *et al.*, 1978).

A crystal of (Z)-perchlorostilbene was mounted on a glass fiber in a random orientation. Cell constants and an orientation matrix for data collection were obtained from least-squares refinement. The data were collected at room temperature; the backgrounds were obtained by analysis of the scan profile (Blessing, Coppens & Becker, 1974). A linear decay correction was applied (from 1.000 to 1.043 on  $I$ ). The agreement factors for the averaging of the 306 reflections were 1.4% based on intensity and 1.3% based on  $F_o$ . The structure was solved using direct methods (Main *et al.*, 1980) and was refined by full-matrix least-squares methods where the function minimized was  $\sum w(|F_o| - |F_c|)^2$ . Anomalous dispersion effects were included in  $F_c$  (Ibers & Hamilton, 1964); the values for  $f_o$  and  $f_c$  were those of Cromer & Waber (1974). Only reflections having intensities greater than 3.0 times their standard deviation and acceptable  $w(\Delta F)^2$  were used in the refinements. Seven points were rejected on the basis of the latter criterion. The errors of maxima and minima in the final difference Fourier were estimated at 0.09, based on  $\Delta F$  (Cruickshank, 1949). The analysis of statistical data based on the collection,  $\sin\theta/\lambda$ , and various classes of indices showed no unusual trends. All X-ray calculations were performed on a MicroVAX 3100 computer using *MolEN* (Fair, 1990).

The support and cooperation from the University of Toledo, College of Arts and Sciences X-ray Facility, A. A. Pinkerton and Professor Douglas A. Smith, for use of the X software obtained through a grant from Molecular Simulations, Inc., are gratefully acknowledged. DL and RF thank the Deutsche Forschungsgemeinschaft for sup-

port (Le 288/14). We thank the College of Arts and Sciences of the University of Toledo for generous financial support of the X-ray diffraction facility.

(Received 13 April 1993; accepted 8 June 1993)

## Abstract

Despite extensive substitution, the dimensions of the planar phenazine rings remain very close to those of the unsubstituted molecule [Woźniak, Kariuki & Jones (1991). *Acta Cryst.* **C47**, 1113-1114]. Typically, the molecules form stacks in which fluorinated rings overlap methylated rings of adjacent molecules.

## Comment

The structure determination was undertaken to establish beyond doubt the identity of unexpected products encountered during an extension (Banks & Madany, 1993) of studies on the trapping of thermally generated perfluoroaryl nitrenes in the trapping of thermally generated perfluoroaryl nitrenes with 1,3,5-trimethylbenzene (Banks & Madany, 1985) and aniline (Banks & Prakash, 1974). Formation of the azo compound (1) can be ascribed to trapping of the incipient singlet nitrene 4-CF<sub>3</sub>C<sub>6</sub>F<sub>4</sub>N by the electron-rich 2,4,6-trimethylaniline (Banks & Prakash, 1974). The dibenzo[1,2]diazepine (2) is known to be produced via the thermal intramolecular dehydrofluorination of (1) (Alty, Banks, Fishwick, Pritchard & Thompson, 1984). However, just how the phenazine (3) arises is not

clear. Thermal oxidative cyclization of non-fluorinated azobenzenes to phenazines in the presence of ferrous oxalate has been reported (Abramovitch & Davis, 1968), but
