## 3-(Benzoylamino)propanoic Acid and 6-[(4-Nitrobenzoyl)amino|hexanoic Acid

N. Feeder and W. Jones*<br>Department of Chemistry, University of Cambridge, Lensfield Road, Cambridge CB2 IEW, England

(Received 2 July 1992; accepted 7 October 1993)

## Abstract

For both structures, $\mathrm{C}_{10} \mathrm{H}_{11} \mathrm{NO}_{3}$ (I) and $\mathrm{C}_{13} \mathrm{H}_{16} \mathrm{~N}_{2} \mathrm{O}_{5}$ (II), there is one molecule in the asymmetric unit. The hydrogen bonding differs from other carboxylic acid amides studied by us in that the acid dimer motif is not observed and, instead, acid-amide hydrogen bonds are formed.

## Comment

As part of a general study of the stability of organic peracids and peracid salts (Kariuki \& Jones, 1992), and in particular of the role of hydrogen bonding in controlling the crystal structure of peracid and acid amides (Feeder \& Jones, 1992), we report here the structures of two aliphatic ( $N$-benzoyl) carboxylic acids, (I) and (II).

(I)

(II)

The bond angles and distances found for both structures are similar to those reported for hippuric acid (Ringertz, 1971), $N$-acetylglycine (Mackay, 1975) and $N$-methylbenzamide (Leiserowitz \& Tuval, 1978). There are, however, subtle differences in molecular conformation between the two structures. Molecules in (I) may be divided into three groups: the benzene ring $A(\mathrm{I})$, the amide group [ $\mathrm{C}(6) \mathrm{C}(7)$ $\mathrm{O}(7) \mathrm{N}(1) \mathrm{C}(8)] B(\mathrm{I})$ and the aliphatic acid group $[\mathrm{C}(9) \mathrm{C}(10) \mathrm{O}(101) \mathrm{O}(102) \mathrm{H}(102)] C(\mathrm{I})$. These groups are each planar to within $0.007,0.007$ and $0.025 \AA$, respectively. $\mathrm{N}(1)-\mathrm{C}(8)-\mathrm{C}(9)-\mathrm{C}(10)$ has a torsion
angle of $61.5^{\circ}$; dihedral angles are $A(\mathrm{I}) B(\mathrm{I}) 3.4$, $B(\mathrm{I}) C(\mathrm{I}) 95.7$ and $A(\mathrm{I}) C(\mathrm{I}) 82.6^{\circ}$.
In (II), the carboxyl group and the alkyl chain are not coplanar, and hence are described as two separate groups, $D$ (II) and $E$ (II), respectively. The benzene ring and nitro group are almost coplanar such that the angle between them is $2.5^{\circ}$ - slightly less than the $7.5^{\circ}$ found for $p$-nitrobenzamide ( Di Rienzo, Domenicano \& Serantoni, 1977) - hence the group as a whole, $A(\mathrm{II})$, is planar to within $0.036 \AA$. The amido group $[\mathrm{C}(6) \mathrm{C}(7) \mathrm{O}(7) \mathrm{N}(1) \mathrm{C}(8)] B(\mathrm{II})$ and alkyl chain $[\mathrm{C}(8) \mathrm{C}(9) \mathrm{C}(10) \mathrm{C}(11) \mathrm{C}(12)] E(\mathrm{II})$ are planar to within 0.014 and $0.039 \AA$, respectively. The dihedral angles are $A(\mathrm{II}) B(\mathrm{II}) 9.0, B(\mathrm{II}) E(\mathrm{II}) 12.4$ and $A($ II $) E($ II $) 21.2^{\circ}$. The carboxyl group [C(13)O(131)$\mathrm{O}(132)] D$ (II) makes angles of $13.6,7.5$ and $9.9^{\circ}$ with $A(\mathrm{II}), B(\mathrm{II})$ and $E(\mathrm{II})$, respectively.

(a)

(b)

Fig. 1. Atom-numbering scheme for (a) (I) and (b) (II).

Structures (I) and (II) exhibit similar hydrogenbond networks. In neither case is the (carboxylic acid) dimer motif observed. This is in contrast to other comparable 'acid amides' previously studied by us (Feeder \& Jones, 1993), where additional hydro-

Fig. 2. (a) The hydrogen-bond network for the structure of (I), viewed down the $a$ axis. The shaded atoms represent one chain. (b) Packing of the blocks produced by hydrogen bonding in the structure of (I), viewed down the $b$ axis.
gen bonding through amide-amide contacts extends the network to form ribbons or sheets. For (I) and (II), however, an arrangement similar to that of N -acetylglycine (Mackay, 1975) is seen, involving acid-amide and amide-acid hydrogen bonds.

Fig. 2(a) is a PLUTO (Motherwell \& Clegg, 1978) plot of (I), depicting the intermolecular hydrogenbonding pattern. Molecules related by a $b$ glide are hydrogen bonded through the carboxyl proton to the amido carbonyl group ( $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}=\mathrm{C}$ 1.679, $\mathrm{O} \cdots \mathrm{O}=\mathrm{C} 2.619 \AA$ ) yielding a chain-like arrangement. These chains are then involved in additional hydrogen bonding through amido proton to carboxyl carbonyl interactions, forming a 12 -membered centrosymmetric ring dimer ( $N-\mathrm{H} \cdots \mathrm{O}=\mathrm{C} 2.070$, $\mathrm{N} \cdots \mathrm{O}=\mathrm{C} 2.960 \AA$ ). Fig. $2(b)$ shows that, as a result of hydrogen bonding, 'blocks' are formed, which are stacked along the $a$ axis and held together by $\pi-\pi$ interactions between the benzene rings.

Fig. 3 is a PLUTO plot of (II), showing a similar intermolecular hyrogen-bonding pattern to that seen for (I). Acid proton to amido-carbonyl group hydrogen bonds result in chains of molecules related by a twofold screw axis ( $\mathrm{O} \cdots \mathrm{O}=\mathrm{C} 2.593 \AA$ ). Again chains related by a centre of symmetry are hydrogen bonded through amido proton to carboxyl carbonyl interactions forming an 18 -membered ring dimer $(\mathrm{N}-\mathrm{H} \cdots \mathrm{O}=\mathrm{C} 1.945, \mathrm{~N} \cdots \mathrm{O}=\mathrm{C} 2.997 \AA$ ). The result of hydrogen bonding is therefore to generate blocks of molecules as in (I).

Fig. 3. The hydrogen-bond network for the structure of (II), viewed down the $a$ axis.

Packing restrictions determine, in both structures, the conformation of the alkyl chain. In (I), the $\mathrm{N}(1)-\mathrm{C}(8)-\mathrm{C}(9)-\mathrm{C}(10)$ and $\mathrm{C}(8)-\mathrm{C}(9)-\mathrm{C}(10)-$ $\mathrm{O}(102)$ torsion angles are very much less than $180^{\circ}$, which probably helps to stabilize the hydrogenbonded dimer. In (II), the hydrogen-bonded chains can only form via the twofold screw operation if the carboxyl group adopts the uncommon anti-planar conformation (Leiserowitz, 1976).

## Experimental

Crystals of (I) were obtained during the attempted recrystallization of the corresponding peracid from glacial acetic acid; crystals of (II) were obtained from a glacial acetic acid solution.

Standard reflections were recentred every 100 reflections and scanned every hour to check for crystal movement and stability. The structures were solved by direct methods using SHELXS86 (Sheldrick, 1985) and refined by full-matrix least-squares analysis using SHELX76 (Sheldrick, 1976). For (I), the amino and carboxylic H -atom coordinates were located from a difference Fourier synthesis and refined with isotropic displacement parameters; ring and alkyl H atoms were fixed geometrically and refined with isotropic displacement parameters. For (II), the ring, alkyl and amino H atoms were fixed geometrically and refined with isotropic displacement parameters. The carboxylic H atom could not be located. All non-H atoms were refined with anisotropic displacement parameters. For (II), only very thin needles were obtained. As a result the data set was weak with an associated high $R$ factor for the final solution.

We acknowledge support from the SERC (studentship for NF). We are grateful to Solvay Interox PLC (and in
particular Dr A. James) for the provision of samples and numerous discussions.

Lists of structure factors, anisotropic displacement parameters, H-atom coordinates and complete geometry have been deposited with the British Library Document Supply Centre as Supplementary Publication No. SUP 71730 ( 26 pp.). Copies may be obtained through The Technical Editor, International Union of Crystallography, 5 Abbey Square, Chester CH1 2HU, England. [CIF reference: HU1017]

(Received 2 July 1992; accepted 7 October 1993)

## Abstract

Two polymorphs of 6-oxo-6-(phenylamino)hexanoic acid, $\mathrm{C}_{12} \mathrm{H}_{15} \mathrm{NO}_{3}$, have been observed. In the first, (I), intermolecular hydrogen bonds form ribbons of molecules, while in the second, (II), a more planar molecular conformation allows the hydrogen bonding to extend to form sheets. The structure of (III), $\mathrm{C}_{11} \mathrm{H}_{13} \mathrm{NO}_{3}$, is also presented and, as a result of the N -methyl substitution, hydrogen bonding is restricted to the formation of carboxylic acid dimers.
