Bis[aqua(15-crown-5)sodium] Bis[(15-crown-5)sodium] Hexaiodotetracopper(I) Tetraiododicopper(I)

GUOZHI HU AND ELIZABETH M. HOLT

Department of Chemistry, Oklahoma State University,
Stillwater, Oklahoma 74078, USA

(Received 13 December 1993; accepted 18 May 1994)

Abstract

$[Na(C_{10}H_{20}O_5)]_2[Na(C_{10}H_{20}O_5)(H_2O)]_2[Cu_2I_4][Cu_4I_6]$ crystallizes with two different copper(I) halide motifs in the unit cell: a polymer of edge-sharing Cu_2I_2 rhombs in which the tetrahedral Cu atoms of every second rhomb are bridged by an additional I atom (which projects alternately up and down) $[Cu—I\ 2.706(3)\ \text{\AA}\ \text{average}]$ and a discrete planar rhomb in which two trigonal planar Cu

atoms, each of which is bonded to a terminal I atom $[Cu—I_{\text{terminal}}\ 2.484(3)\ \text{\AA}]$, are bridged by another two I atoms $[Cu—I_{\text{bridging}}\ 2.572(4)\ \text{\AA}\ \text{average}]$. While both motifs have been seen independently in other crystalline materials, the observation of the two in one material is highly unusual. Four 15-crown-5 rings, each coordinated to an Na atom $[Na—O\ 2.42(2)\ \text{\AA}\ \text{average}]$, balance the charge within the asymmetric unit. Two of the Na(15-crown-5) groups have a water molecule coordinated to the metal atom $[Na—O\ 2.29(2)\ \text{\AA}]$. The remaining two Na(15-crown-5) groups display $Na \cdots I_{\text{terminal}}$ distances of $3.220(8)\ \text{\AA}$. In the crown ether the average C—O distance is $1.392(3)\ \text{\AA}$ and the average C—C distance is $1.48(5)\ \text{\AA}$. Cu \cdots Cu separations are $2.472\ \text{\AA}$ when the two Cu atoms have three bridging I atoms (within the polymeric unit) and average $2.660(5)\ \text{\AA}$ when the pair of Cu atoms are bridged only by two I atoms (as seen in the polymeric unit and the discrete dimer).

Comment

Many copper halide complexes of the formula $Cu_xX_z^{-(z-y)}$, where $X = Cl, Br, I$, have been identified. They may be discrete, for example, tetrahedral $Cu_4X_6^{2-}$ or rhombohedral $Cu_2I_4^{2-}$, or polymeric $(Cu_2I_3)_x$ (Jagner & Helgesson, 1991). While the incidence of the copper halide motif is apparently influenced by the size and shape of the cation, there are many cases where the same cation is observed with different copper halide motifs in different crystals and, indeed, a synthetic product often contains several of these. However, it is very unusual to observe more than one copper halide motif within the same unit cell, as in the title compound (I) (Fig. 1). $K_7(12\text{-crown-4})_6Cu_4I_6^{5-}(Cu_8I_{13})^{5-}$ (Rath & Holt, 1985), in which two discrete copper(I) halide clusters exist in the asymmetric unit with a tetrahedron of Cu atoms with edge-bridging I atoms and a cubic arrangement of eight Cu atoms centered about an I atom with all cube edges bridged by an I atom, is the only other known example.

The $Cu_2I_3^-$ motif, a polymeric series of edge-sharing Cu_2I_2 rhombs with alternate rhombs bridged by an additional I atom, exists as two versions in the literature differing in the pattern of direction of projection of the bridging I atom. An alternating 'up, down, up, down' pattern of projection has been observed for (tetramethylammonium) Cu_2I_3 (Andersson & Jagner,

1985a), (tetraethylammonium) Cu_2I_3 and [dimethyl(3-dimethylamino-2-aza-2-propenylidene)ammonium] Cu_2I_3 (Hartl & Mahdjour-Hassan-Abadi, 1981). The title structure is of this type (Fig. 2). However, (2,4,6-triphenylthiopyrylium) Cu_2I_3 (Batsanov, Struchkov, Ukhin & Dolgoplova, 1982) and $\text{K}(15\text{-crown-5})\text{Cu}_2\text{I}_3$ (Rath & Holt, 1985) both display an 'up, up, down, down' bridging pattern. Each of these structures displays a weak ionic interaction with the bridging I atom (in the former, $\text{S} \cdots \text{I}$, and $\text{K} \cdots \text{I}$ in the latter) which undoubtedly influences the conformation of the polymer.

Both conformations display $\text{Cu} \cdots \text{Cu}$ separations across rhombs which are shorter when the pair of Cu atoms is bridged by three I atoms and longer when the rhomb lacks the third bridging I atom.

Cu_2X_4 has been observed in the solid state for Cl, Br and I, while the Cu_2X_3 motif is known only with $\text{X} = \text{I}$.

As the terminal $\text{Cu}-\text{X}$ distance is always shorter than the bridging $\text{Cu}-\text{X}$ distance, the $\text{Cu}-\text{X}-\text{Cu}$ bridge sometimes displays unequal bond distances. Flexibility of the rhomb is indicated by the range of $\text{Cu} \cdots \text{Cu}$ separations observed: 2.660 (3)–2.937 (3) Å. The rhomb may be planar or folded about the bridging halide atoms. Planar rhombs are observed in $[\text{VO}(\text{SALen})\text{H}_2\text{O}]_2\text{Cu}_2\text{Cl}_4$ (Banci, Bencini, Dei & Gatteschi, 1984), bis(phenyltrimethylammonium) Cu_2Br_4 (Andersson & Jagner, 1985b), bis(methyltriphenylphosphonium) Cu_2Br_4 (Andersson & Jagner, 1987b), bis(tet-

raethylammonium) Cu_2Br_4 (Asplund & Jagner, 1984a), bis(tetraethylphosphonium) Cu_2Br_4 (Andersson & Jagner, 1987a), TTCu_2Br_4 (Shibaeva & Kaminskii, 1981), bis(tetrabutylammonium) Cu_2I_4 (Asplund, Jagner & Nilsson, 1982) and bis(tetrapropylammonium) Cu_2I_4 (Asplund & Jagner, 1984b), whereas bis(tetraphenylarsonium) Cu_2I_4 (Asplund & Jagner, 1984b) displays a fold angle of $146.61(4)^\circ$ and both planar and nonplanar (fold angle 146.34°) bis(tetraphenylphosphonium)- Cu_2I_4 (Hartl, Brudgam & Mahjour-Hassan-Abadi, 1985) have been reported.

Experimental

CuI (0.38 g, 2 mmol) was dissolved in 20 ml of saturated NaI solution with ascorbic acid added to retard copper oxidation. Acetone (20 ml) and 15-crown-5 (1 ml, 5 mm) were added resulting in a yellow solution which was heated to reflux under nitrogen for 5 h, cooled to ambient temperature and filtered. Colorless needles formed on cooling the filtrate to 278 K for 48 h.

Abstract

The title complex, (C₁₅H₁₁S₂)[AuI₂], consists of a 3,5-diphenyldithiolium cation and a diiodoauride anion. The Au^I center is linearly coordinated by two I atoms.
