The  $\omega$  scan width was symmetrical over  $1.2^\circ$  about the  $K\alpha_{1,2}$  maximum and the background was offset 1.0 and  $-1.0$  in  $\omega$  from the  $K\alpha_{1,2}$  maximum. The scan speed was a variable  $3-6^\circ \text{ min}^{-1}$  (depending upon intensity). The linear absorption coefficient was calculated using values from *International Tables for X-ray Crystallography* (1974, Vol. IV).

The structure was solved by the heavy-atom method from which the position of the Ni atom was found. The remainder of the non-H atoms were obtained from a difference Fourier map. The amide H and aromatic H atoms were obtained from a subsequent difference Fourier map and refined without constraints; their distances range from 0.86 (4) to 0.99 (4) Å, and their angles between  $117(2)$  and  $121(2)^\circ$ , except for atom H10 which makes angles of  $114(2)$  and  $127(2)^\circ$ . Their isotropic displacement parameters range from 0.043 (9) to  $0.073(12) \text{ \AA}^2$ . The methyl H atoms were calculated in idealized positions (0.96 Å) and given fixed displacement parameters.

Programs used: *SHELXTL-Plus* (Sheldrick, 1990) for cell refinement, data collection, data reduction, structure solution (direct methods) and molecular graphics; *SHELX76* (Sheldrick, 1976) for structure refinement (full-matrix least squares); *FUER* (Larson, 1982) for geometric and parameter tables.

The authors would like to acknowledge the University of Florida, Division of Sponsored Research, for support of the crystallography work, and the donors of the Petroleum Research Fund, administered by the American Chemical Society.

Lists of structure factors, anisotropic displacement parameters, H-atom coordinates and bond distances and angles involving H atoms have been deposited with the IUCr (Reference: BK1063). Copies may be obtained through The Managing Editor, International Union of Crystallography, 5 Abbey Square, Chester CH1 2HU, England.

## Abstract

In *cis*-[PdCl<sub>2</sub>(Ph<sub>2</sub>PCH<sub>2</sub>CH<sub>2</sub>PPh<sub>2</sub>)], the Pd atom is at the centre of an approximately square-planar arrangement of two P and two Cl atoms. The P—Pd—P angle is  $88.3(1)^\circ$  and the two Pd—P distances are 2.284 (3) and 2.264 (3) Å.

### Comment

Only a few complexes are known in which SbCl<sub>3</sub> acts as a donor, e.g. [Ni(CO)<sub>3</sub>].SbCl<sub>3</sub> and [Fe(CO)<sub>3</sub>].(SbCl<sub>3</sub>)<sub>2</sub> (Wilkinson, 1951). It was intended to explore the donor property of SbCl<sub>3</sub> further by reacting it with the d<sup>8</sup> square-planar complex [PdCl<sub>2</sub>(dppe)] (dppe = Ph<sub>2</sub>PCH<sub>2</sub>CH<sub>2</sub>PPh<sub>2</sub>). The 1:1 molar reaction of [PdCl<sub>2</sub>(dppe)] with SbCl<sub>3</sub> yielded a diamagnetic complex of the composition [PdCl<sub>2</sub>(dppe)].SbCl<sub>3</sub>. In order to obtain a single crystal for X-ray diffraction work, this complex was recrystallized from a mixture of CH<sub>2</sub>Cl<sub>2</sub> and hexane. However, the composition of the crystals thus obtained proved to be [PdCl<sub>2</sub>(dppe)], (I), and not [PdCl<sub>2</sub>(dppe)].SbCl<sub>3</sub>. Nevertheless, we decided to determine the crystal structure of [PdCl<sub>2</sub>(dppe)] to compare it with that of [PdCl<sub>2</sub>(dppe)].CH<sub>2</sub>Cl<sub>2</sub> (Steffen & Palenik, 1976).

The crystals of the title complex are monoclinic and belong to the same space group (*P*2<sub>1</sub>/*c*) as those of [PdCl<sub>2</sub>(dppe)].CH<sub>2</sub>Cl<sub>2</sub> (Steffen & Palenik, 1976). However, packing of the molecules in the unit cells of the solvated and unsolvated complexes is different. The unit-cell volume and density of the non-solvated complex are less than those of the solvated complex. Similar results have been reported in the analogous cases of [ReCl<sub>2</sub>(C<sub>26</sub>H<sub>22</sub>P<sub>2</sub>)<sub>2</sub>].C<sub>6</sub>H<sub>14</sub> (Lewis,

Luck & Silverton, 1993) and [ReCl<sub>2</sub>(C<sub>26</sub>H<sub>22</sub>P<sub>2</sub>)<sub>2</sub>] (Bakir, Fanwick & Walton, 1986). Another interesting observation is that the Pd—P bond lengths and P—Pd—P angle are larger in the present case than in that of the solvated complex, viz. Pd—P1 and Pd—P2 are 2.284 (3) and 2.264 (3) Å, respectively, compared with 2.233 (2) and 2.226 (2) Å, respectively, in the solvated complex, and the P—Pd—P angle is 88.3 (1)° compared with 85.82 (7)° in the solvated complex. In addition, some P—C bond lengths are longer in the unsolvated complex. These differences may arise from the packing effects of the solvent molecule.

Data were corrected for Lorentz and polarization factors. The structure was solved by direct methods with *SHELXS86* (Sheldrick, 1985). The structure was refined using *SHELXL76* (Sheldrick, 1976). H atoms were fixed geometrically. The perspective view of the title molecule was drawn using *ORTEPII* (Johnson, 1976) and geometrical analysis was performed using *PARST* (Nardelli, 1983).

Lists of structure factors, anisotropic displacement parameters, H-atom coordinates and complete geometry have been deposited with the IUCr (Reference: MU1120). Copies may be obtained through The Managing Editor, International Union of Crystallography, 5 Abbey Square, Chester CH1 2HU, England.

## Abstract

The title complex,  $[\text{Ni}(\text{N}_3)(\text{C}_3\text{H}_9\text{P})_4]\text{BF}_4$ , is a nearly perfect trigonal bipyramid with the azide group at an apical position. The metal–azide bond angle,  $\text{Ni1—N1—N2}$ , of  $138.6(5)^\circ$  is the largest observed for a terminal azide ligand.

## Comment

Nickel(0) and nickel(I) reagents have significant utility in aryl-coupling reactions (Zembayashi, Tamao, Yoshida & Kumada, 1977; Semmelhack *et al.*, 1981; Rollin, Troupel, Tuck & Perichon, 1986; Amatore & Jutand, 1988; Zhou & Yamamoto, 1991). A potential source of such low-valency metal complexes are metal azides. This results from the ability of the azide to undergo photo-induced reductive elimination. As part of a study of nickel–azide–phosphine complexes, the azido-tetrakis(trimethylphosphine)nickel(II) cation was synthesized as its  $\text{BF}_4^-$  salt, (1), and examined by X-ray crystallography. To our knowledge, this species is the only known five-coordinate nickel–azide complex.
