### Abstract

The donor–acceptor complex  $C_9H_3F_5O_2 \cdot C_{11}H_{13}NO_2$  crystallizes as carboxy-hetero dimers which are stacked to optimize  $\pi \cdots \pi$  interactions. Additionally C—H $\cdots$ O, C—H $\cdots$ F, O $\cdots$ F and F $\cdots$ F interactions are important.

### Comment

Charge-transfer molecular complexes of cinnamic acids are of interest because of their possible solid-state reactivity (Sarma & Desiraju, 1985). The  $\pi \cdots \pi$  interactions between two electronically different cinnamic acids have been exploited in the preparation of asymmetric truxinic acids in the solid state; these acids are good candidates for molecular recognition in host–guest complexes (Weber, Hecker, Csoregh & Czugler, 1989; Desiraju & Sharma, 1991; Sharma, Panneerselvam, Pilati & Desiraju, 1993). The title molecular complex (1) was prepared with the aim of engineering a solid-state reaction. Complex (1) is, however, unreactive upon photoirradiation in the solid state and this led us to study its structural features.

Acids *A* (2,3,4,5,6-pentafluoro-*trans*-cinnamic acid) and *B* [4-(*N,N*-dimethylamino)-*trans*-cinnamic acid] in (1) are hydrogen bonded through carboxyl groups to form a hetero dimer. The O $\cdots$ O distances are 2.61–2.62 Å. The carboxyl groups are partially disordered in the molecule of *A* with C(9)—O(2) 1.246 (2) Å, C(9)—O(1) 1.290 (2) Å, O(2)—C(9)—C(8) 121.6 (2) $^\circ$ , O(1)—C(9)—C(8) 114.9 (2) $^\circ$  and also in the molecule of *B* with C(9)—O(2) 1.251 (2) Å, C(9)—O(1) 1.293 (2) Å, O(2)—C(9)—C(8) 121.7 (2) $^\circ$ , O(1)—C(9)—C(8) 115.8 (2) $^\circ$ . This disorder is caused by the comparable crystal environments around the O(1) and O(2) atoms, especially with regard to their C—H $\cdots$ O hydrogen-bond forming ability (Leiserowitz, 1976; Goud, Pathaneni & Desiraju, 1993). These hetero dimers are stabilized by C—H $\cdots$ O and C—H $\cdots$ F interactions and form a sheet-like structure along (101) (Fig. 2). These sheets are stacked using  $\pi \cdots \pi$  interactions (Fig. 3). Evidence for these interactions is obtained from the deeper colour of the complex (dark yellow) when compared with its constituents (acid *A* is white and *B* is light yellow). Interestingly, the donor–acceptor phenyl rings of the *A* and *B* molecules do not overlap but instead have a large lateral offset such that  $\pi \cdots \pi$  interactions between the aromatic ring and the double bond are optimized. This is a rare occurrence (Sharma *et al.*, 1993).

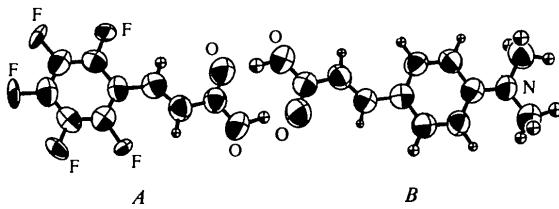

Fig. 1. ORTEPII (Johnson, 1976) view of complex (1) showing the atom-labelling scheme. Displacement ellipsoids are plotted at the 50% probability level.

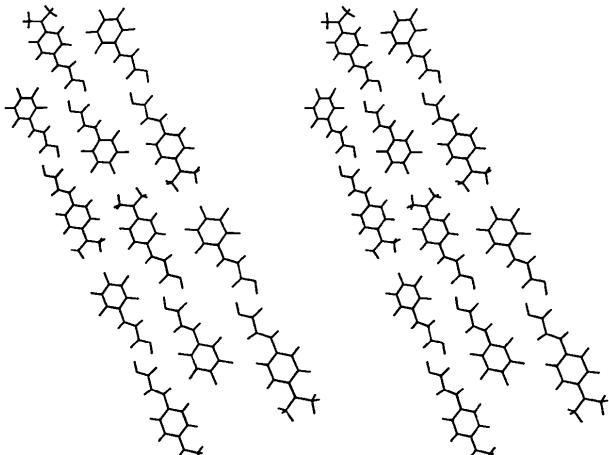

Fig. 2. Molecular complex (1) viewed along (101) to show the sheet structure.

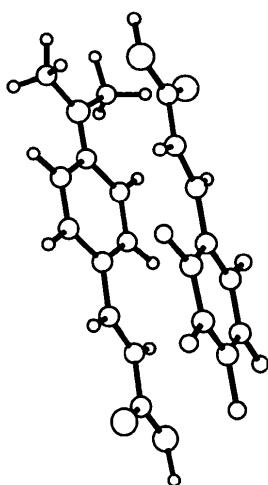

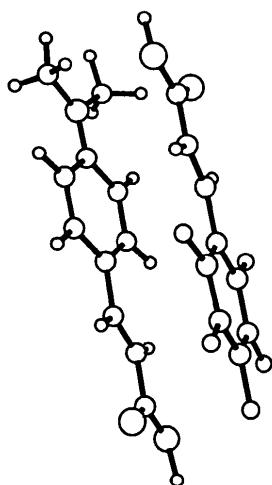

Fig. 3.  $\pi \cdots \pi$  stacking in the donor–acceptor complex (1).

The phenyl–phenyl centroid-to-centroid distance is 4.84 Å and the mean plane-to-plane distance is 3.34 Å. For this reason, the two double bonds of the stacked donor and acceptor molecules are separated by 5.0 Å, which exceeds the photochemical reaction threshold distance for 2 + 2 cycloaddition (Schmidt, 1964). The C—F distances (Table 2) are typical. The mean C—F distance in a collection of 293 fluoro-substituted aromatic compounds from the Cambridge Structural Database (1994; Version 5.07) was found to be 1.344 Å with 96% of the lengths being clustered in the range 1.295–1.385 Å. F···F contacts of 2.76 Å are formed between inversion-related F atoms, but C—H···F contacts seem to be more important because of the greater electronegativity of the F atoms. All these interactions stabilize the crystal structure of complex (1).

## Experimental

Dark-yellow crystals of the 1:1 complex (1) (m.p. 441–442 K) were obtained exclusively by slow evaporation of an equimolar solution of acid A (m.p. 423 K) and acid B (m.p. 498 K) in 1:2 EtOAc–benzene. The acids A and B were themselves prepared from the corresponding aldehydes by literature procedures.

## 3,5-Diamino-6-(2-methylphenyl)-1,2,4-triazine Monohydrate: an Analogue of Lamotrigine

ROBERT W. JANES AND R. A. PALMER

Department of Crystallography, Birkbeck College, University of London, Malet Street, London WC1E 7HX, England

(Received 9 May 1994; accepted 6 December 1994)

## Abstract

The asymmetric unit of  $2\text{C}_{10}\text{H}_{11}\text{N}_5\text{H}_2\text{O}$  contains two conformers of the triazine molecule and a water molecule; each conformer has distinct dihedral angles between the respective phenyl and triazine rings [100.8 (1) and 61.7 (1) $^\circ$ ]. These two conformers exhibit significant differences in certain bond lengths and angles which may arise because of their different dihedral angles. Although crystallized from acetonitrile, the extensive hydrogen-bonding network that maintains the crystal structure incorporates a water molecule.

## Comment

The molecule studied is an analogue of the anticonvulsant 3,5-diamino-6-(2,3-dichlorophenyl)-1,2,4-triazine, known as lamotrigine (Janes, Lisgarten & Palmer, 1989), and was supplied by Wellcome Pharmaceuticals (UK). The structure was determined as part of an on-going investigation into structure–activity studies on a series of lamotrigine analogues (Janes & Palmer,
