(Received 27 September 1994; accepted 21 December 1994)

#### Abstract

Ceric potassium nitrate, $\mathrm{K}_{2} \mathrm{Ce}\left(\mathrm{NO}_{3}\right)_{6}$, was synthesized from the dissolution in nitric acid of active hydrous ceria and potassium nitrate in stoichiometric quantities. Two forms, with hexagonal and monoclinic symmetries, have been isolated. The structures were solved by single-crystal X-ray diffraction analyses. They consist of discrete $\left[\mathrm{Ce}\left(\mathrm{NO}_{3}\right)_{6}\right]^{2-}$ anions in the form of irregular icosahedra, in which Ce atoms are twelvefold coordinated by six bidentate nitrate groups. The K atoms ensure the continuity of the structures by ionic contacts. Relationships between the two structures are described briefly.

## Comment

The present structure investigations were performed as part of a detailed study into the mechanisms of thermal decomposition of precursors of cerium oxide, $\mathrm{CeO}_{2}$, based on Ce ${ }^{\mathrm{TV}}$ nitrates (Guillou, 1994; Guillou, Auffrédic \& Louër, 1994). The high oxidation power of $\mathrm{Ce}^{\mathrm{IV}}$ compounds is also one of the interesting properties of this kind of material. For instance, ceric ammonium nitrate, $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{Ce}\left(\mathrm{NO}_{3}\right)_{6}$, has been used as an oxidant standard and in the conversion of some alcohols and toluenes in aldehydes (see Trahanovsky, Young \& Brown, 1967). Its crystal structure has been determined by Beineke \& Delgaudio (1968), and chemically related compounds with alkaline elements ( $\mathrm{K}, \mathrm{Rb}, \mathrm{Cs}$ ) were reported many years ago (Meyer \& Jacoby, 1901). The determination of the unit-cell parameters from X-ray powder diffraction data of the mixed ceric caesium and ceric rubidium nitrates has suggested that these two compounds are isostructural with ceric ammonium nitrate (Guillou, Auffrédic \& Louër, 1993).

In the case of ceric potassium nitrate, two crystalline $\mathrm{K}_{2} \mathrm{Ce}\left(\mathrm{NO}_{3}\right)_{6}$ phases were identified in the system $\mathrm{CeO}_{2-}$ $\mathrm{HNO}_{3}-\mathrm{KNO}_{3}-\mathrm{H}_{2} \mathrm{O}$. From this study, single crystals of the two varieties could be isolated. One of them, (I), has
hexagonal symmetry, while the other, (II), is monoclinic. Both structures comprise discrete $\left[\mathrm{Ce}\left(\mathrm{NO}_{3}\right)_{6}\right]^{2-}$ anions in the form of irregular icosahedra, in which Ce atoms are linked to six bidentate nitrate groups (Figs. $1 \& 2$ ). The mean $\mathrm{Ce}-\mathrm{O}$ distances [ 2.506 (I), $2.507 \AA$ (II)] are in agreement with the value ( $2.475 \AA$ ) calculated by the bond-valence method (Brown, 1981) for $\mathrm{Ce}^{\mathrm{IV}}$ bonded to 120 atoms. They are also close to the mean value ( $2.508 \AA$ ) found for the structure of $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{Ce}\left(\mathrm{NO}_{3}\right)_{6}$ (Beineke \& Delgaudio, 1968).

As shown in Fig. 1, the $\left[\mathrm{Ce}\left(\mathrm{NO}_{3}\right)_{6}\right]^{2-}$ groups are located at the origin of the cell and along a threefold axis in the hexagonal phase, while they are in a body-

Fig. 1. View of the unit cell of the two polymorphic (a) hexagonal and (b) monoclinic forms of $\mathrm{K}_{2} \mathrm{Ce}\left(\mathrm{NO}_{3}\right)_{6}$. Large circles correspond to K atoms.

Fig. 2. Projections of the two structures of $\mathrm{K}_{2} \mathrm{Ce}\left(\mathrm{NO}_{3}\right)_{6}(a)$ along $\mathbf{c}$ for the hexagonal form and (b) along $b$ for the monoclinic form.
centred arrangement in the monoclinic phase. For the two compounds, the three independent nitrate groups are symmetrically bidentate and belong to the class $\mathrm{I}_{2 b}$, proposed by Leclaire (1979). As found for this class of nitrate compounds, the distances from the N atom to the non-coordinated $\mathbf{O}$ atom are significantly shorter [mean values: 1.210 (I), $1.211 \AA$ (II)] than the other
$\mathrm{N}-\mathrm{O}$ distances [mean values: 1.274 (I), $1.272 \AA$ (II)]. The displacement parameters of these free O atoms are greater than those of the coordinated $O$ atoms, and the $\mathrm{O}-\mathrm{N}-\mathrm{O}$ angles between the two coordinated O atoms are smaller than the $\mathrm{O}-\mathrm{N}-\mathrm{O}$ angles involving a free O atom.

The K atoms located between the $\left[\mathrm{Ce}\left(\mathrm{NO}_{3}\right)_{6}\right]^{2-}$ anions ensure the continuity of the structure by ionic contacts. They are surrounded by nine and ten $\mathbf{O}$ atoms for compounds (I) and (II), respectively. It may be noted that the $c$ parameter for (I) is similar to the $b$ axis of the monoclinic form. Projections of the structures along [001] and [010] for (I) and (II), respectively, are shown in Fig. 2, from which the structural relationships between the two varieties can be seen. Indeed, if we consider four hexagonal cells (Fig. 2a), an arrangement like that in the monoclinic cell (Fig. 2b) is found at the intersection of these four hexagonal cells with a translation of $\frac{1}{2}$ along the projection axis. The $\overline{3}$ axis clearly reproduces the monoclinic cell every $60^{\circ}$.

## Experimental

Crystals of $\mathrm{K}_{2} \mathrm{Ce}\left(\mathrm{NO}_{3}\right)_{6}$ were synthesized by evaporation at 313 K of a solution of 0.94 g of potassium nitrate and 1 g of cerium oxide, $\mathrm{CeO}_{2} \cdot 2 \cdot 4 \mathrm{H}_{2} \mathrm{O}$, previously dissolved in boiled concentrated nitric acid in a closed vessel. This synthesis requires a finely divided oxide (Guillou, Auffredic \& Louër, 1994). The hexagonal and monoclinic forms appear simultaneously when the evaporation is fast. The monoclinic form dominates when the crystallization is slow.

Symmetry codes: (i) $1-x, 1-y, 1-z$; (ii) $x-\frac{1}{2}, \frac{1}{2}-y, \frac{1}{2}+z$; (iii) $1-x,-y, 1-z$; (iv) $\frac{1}{2}-x, \frac{1}{2}+y, \frac{1}{2}-z$; (v) $x-\frac{1}{2}, \frac{1}{2}-y, z-\frac{1}{2}$; (vi) $\frac{1}{2}-x, \frac{1}{2}+y, \frac{3}{2}-z$.

Data were corrected for Lorentz-polarization effects. The unitcell dimensions were found by indexing the powder diffraction pattern with the program DICVOL91 (Boultif \& Louër, 1991). The final parameters were refined by the program NBS*AIDS83 (Mighell, Hubbard \& Stalick, 1981). The structure of (I) was solved by the Patterson method (Ce and K) and one subsequent difference Fourier synthesis (all other atoms). For (II), the atomic coordinates of the isostructural compound $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{Ce}\left(\mathrm{NO}_{3}\right)_{6}$ (Beineke \& Delgaudio, 1968) were used as initial coordinates in the refinement. Calculations were performed with the MolEN (Fair, 1990) package on a MicroVAX 3100 computer. Diagrams were prepared using $O R$ TEPII (Johnson, 1976).

The authors are grateful to Dr L. Toupet for his assistance in the collection of the single-crystal X-ray diffraction data.

Lists of structure factors and anisotropic displacement parameters have been deposited with the IUCr (Reference: DU1103). Copies may be obtained through The Managing Editor, International Union of Crystallography, 5 Abbey Square, Chester CH1 2HU, England.

## Abstract

The structure of cerous potassium nitrate, $\mathrm{K}_{3} \mathrm{Ce}_{2}\left(\mathrm{NO}_{3}\right)_{9}$, which can be synthesized from an aqueous solution of cerous nitrate hexahydrate and potassium nitrate, or from a nitric acid solution of hydrated ceria and potassium nitrate, has been solved by single-crystal X -ray diffraction analysis. It comprises an anionic, $\left[\mathrm{Ce}_{2}\left(\mathrm{NO}_{3}\right)_{9}\right]^{3-}$, network of irregular icosahedra formed by bidentate nitrate groups around Ce atoms and linked to one another by bridging nitrate groups. The K atoms are located in the holes of the structure.

## Comment

In a previous study (Guillou, Auffrédic, Louër \& Louër, 1993), it was shown that $\mathrm{Ce}^{\text {III }}$ compounds could be obtained from a solution of hydrated ceria in nitric acid. In the course of the investigation of the system $\mathrm{CeO}_{2}-$ $\mathrm{KNO}_{3}-\mathrm{HNO}_{3}-\mathrm{H}_{2} \mathrm{O}$, a new cerium(III) nitrate compound was obtained. Indeed, from the dissolution in nitric acid of active hydrated ceria and potassium nitrate in stoichiometric quantities (ratio 1:2), colourless crystals appear at 313 K together with crystals of $\mathrm{K}_{2} \mathrm{Ce}\left(\mathrm{NO}_{3}\right)_{6}$, the structures of two polymorphic phases of which have been reported (Guillou, Louër, Auffrédic \& Louër, 1995). An alternative synthesis of the new compound is by the evaporation at 313 K of an aqueous solution of cerous nitrate hexahydrate and potassium nitrate (ratio 2:3). This reaction demonstrates that the new phase is a $\mathrm{Ce}^{\text {III }}$ compound. Furthermore, the crystal structure determination reported here shows that this compound is the tripotassium dicerium(III) nitrate, $\mathrm{K}_{3} \mathrm{Ce}_{2}\left(\mathrm{NO}_{3}\right)_{9}$.

The structure of the title compound (Fig. 1) consists of a three-dimensional $\left[\mathrm{Ce}_{2}\left(\mathrm{NO}_{3}\right)_{9}\right]^{3-}$ network of irregular icosahedra in which Ce atoms are twelvefold coordinated (Fig. 2). The coordination of the Ce atoms involves six bidentate nitrate groups. Three of these nitrate groups each bridge two icosahedra. This network can also be described as spirals running along the $c$ axis (Fig. 3). As a result of the cubic symmetry, these spirals also run along the $a$ and $b$ axes, from which the three-dimensional network arises. The mean $\mathrm{Ce}-\mathrm{O}$ distance ( $2.649 \AA$ ) is similar to the value ( $2.649 \AA$ ) calculated by the bond-valence method (Brown, 1981) for
