One Sn-atom position was solved using the Patterson heavy-atom method. The remaining atoms were located using *DIRDIF* (Beurskens *et al.*, 1984) and in succeeding difference Fourier syntheses. It was not possible to differentiate the hydroxy and the two methyl groups of the 2-phenylpropanol solvent molecule. Hence, these three atoms were refined as C atoms without attached H atoms. All other H atoms were located and included in the structure-factor calculations, but their positions were not refined. The structure was refined by full-matrix least squares, where the function minimized was $\Sigma w(|F_o| - |F_c|)^2$ and the weight *w* is defined as per the Killean & Lawrence (1969) method with the terms 0.20 and 1.0. Anomalous-dispersion effects were included in *F_c* (Ibers & Hamilton, 1964); the values for *f'* and *f''* were those of Cromer (1974). The highest peak in the final difference Fourier map had a height of 0.53 \AA^{-3} with an estimated error based on ΔF (Cruickshank, 1945) of 0.08. All calculations were performed on a VAX computer using *SDP* (Enraf–Nonius, 1985).

We thank the National Science Foundation (grant CHE-8915573) for support of this research.

Abstract

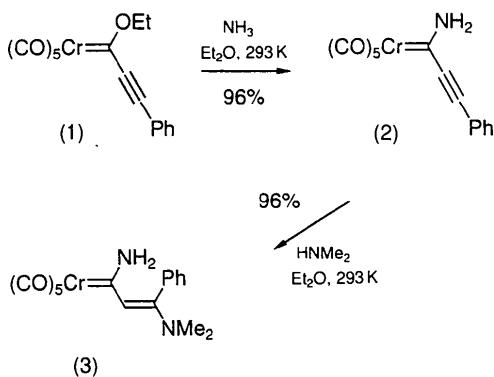

The syntheses and crystal structures of [(2E)-1-amino-3-dimethylamino-3-phenylpropen-1-ylidene]pentacarbonylchromium, [Cr(C₁₁H₁₄N₂)(CO)₅], pentacarbonyl[(2E)-3-dibenzylamino-1-ethoxy-6,6-dimethylhept-2-en-4-ynylidene]chromium, [Cr(C₂₅H₂₉NO)(CO)₅], and pentacarbonyl(4-dibenzylamino-5,5-dimethyl-2,5-dihydro-2-furylidene)chromium, [Cr(C₂₀H₂₁NO)(CO)₅], are reported. All compounds show significant π delocalization over the carbene fragment.

Comment

α,β -Unsaturated (carbene)chromium complexes have become important reagents in synthetic organic chemistry. With appropriate substituents at the carbene C atom and/or the vinyl terminus, they react with alkynes in a number of ways to give various ring systems. The addition of ammonia to (alkynylcarbene)chromium complexes leads either to [(Z)-2-aminoethynyl]carbene complexes or to (1-aminoethynyl)carbene complexes; this can be controlled by temperature variations (Stein, Duetsch, Pohl, Herbst-Irmer & de Meijere, 1993).

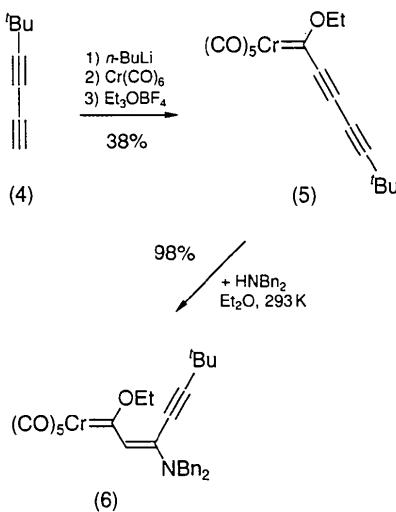

The reaction of (1-ethoxy-3-phenylpropynylidene)-pentacarbonylchromium, (1), with ammonia afforded exclusively the substitution product (2) in 96% yield at

room temperature (Stein, 1993). Michael-type addition of dimethylamine yielded [(*E*)-1-amino-3-dimethylamino-3-phenylpropen-1-ylidene]pentacarbonylchromium, (3), in 96% yield as yellow crystals. The

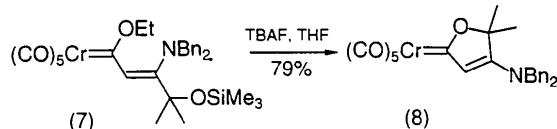

structure was determined by X-ray crystallography to confirm the *E* configuration of the C2=C3 double bond. The bond lengths and angles agree with values found for pentacarbonyl[(2-dimethylaminoethenyl)[(methoxy)phenylmethyleneamino] carbene]chromium (Wienand, Reissig, Fischer & Hofman, 1989). The planar environment of N1 and N4 indicates π delocalization over the N atoms. The mean deviation from the least-squares plane through Cr1, C1, N1, C2, C3, C31 and N4 is 0.193 Å.

The first 1,3-diynylcarbenechromium complex, (5), was synthesized from the hexadiyne (4) in 38% yield (Funke & de Meijere, 1995). The reaction of the complex (5) with dibenzylamine gave a selective Michael-type addition to the C3 atom of (5) and only the *E* isomer of the orange coloured complex (6) (98% yield) was formed; this had to be proved by X-ray crystallography. The ethoxyethenylcarbene ligand is almost planar (the mean deviation from the least-squares plane through Cr, C1, O1, N1, C2, C3 and C4 is 0.055 Å). The C4≡C5 bond distance of 1.195 (3) Å is typical for a C≡C triple bond.

This new functionalized α,β -unsaturated (carbene)-chromium complex (6) is useful for cycloaddition to alkynes, yielding various ring systems with interesting functional groups (Funke & de Meijere, 1995).

Treatment of the dibenzylamino(trimethylsilyloxy)-substituted complex (7) with tetra-*n*-butylammonium fluoride (TBAF) in THF afforded pentacarbonyl(4-dibenzylamino-5,5-dimethyl-2,5-dihydro-2-furylidene)-chromium, (8), in 79% yield, by intramolecular substitution of the ethoxy group (Stein, Duetsch, Noltemeyer & de Meijere, 1993; Lattuada, Licandro, Maiorana, Molinari & Papagni, 1991; Christophers & Dötz, 1993). The structure assignment was confirmed by the X-ray crystal structure determination.

Compound (8) showed very low reactivity towards electrophilic addition of various reagents to the formal C4=C5 double bond. The crystal structure of (8) shows a five-membered central planar ring (the mean deviation from least-squares plane through Cr1, C1, O2, C3, C4, C5 and N6 is 0.015 Å). This planarity, the planar coordination environment around N6, and the bond lengths found for N6—C4, C1—C5 and C1—Cr1 indicate delocalization of the double bond within the core unit.

The carbene fragment in (3) is less planar than in (6) and (8). The shortest C_{carbene}—C_{olefin} distance was found for (8) and the longest for (3); the shortest C=C double bond was observed in (3). This indicates that the degree for π delocalization is highest in (8) and lowest in (3). However, the C_{carbene}—Cr distances are comparable for (3) and (6), but it is significantly shorter in (8), compared with (6) and other O-substituted complexes {e.g. pentacarbonyl[(2E)-3-(diisopropylamino)-1-ethoxy-3-phenylpropylidene]chromium (Duetsch *et al.*, 1992)}.

In general, the C_{carbene}—Cr distances are shorter for the carbene complexes with O substituents than for

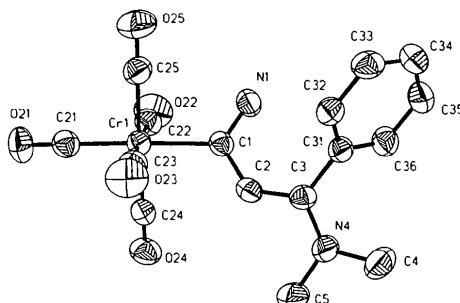

Fig. 1. Structure of (3) showing 50% probability displacement ellipsoids. H atoms are omitted for clarity.

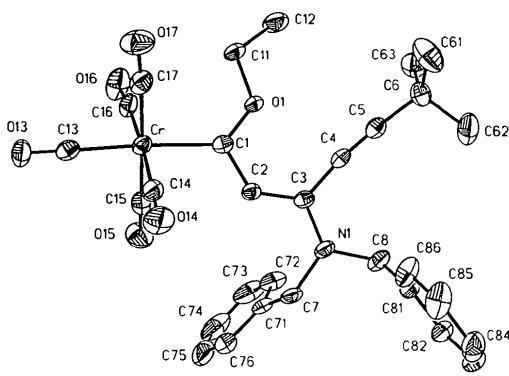

Fig. 2. Structure of (6) showing 50% probability displacement ellipsoids. H atoms are omitted for clarity.

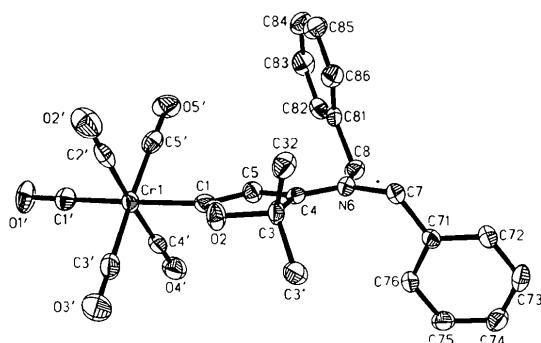

Fig. 3. Structure of (8) showing 50% probability displacement ellipsoids. H atoms are omitted for clarity.

the carbene complexes with N substituents {cf. pentacarbonyl[cyclohexylamino-(1-methoxyvinyl)carbene]chromium (Huttnner & Lange, 1970), pentacarbonyl[(Z)-dimethoxyvinyl]methoxycarbenechromium (Dötz, Kuhn & Thewalt, 1985), pentacarbonyl[(E)-3-(dimethylamino)-1-methoxypropylidene]chromium (Lattuada *et al.*, 1988)}.

All three compounds show almost ideal octahedral coordination around the Cr atom. The C—Cr distance of the carbonyl group *trans* to the carbene centre is between 0.02 and 0.04 Å shorter than the C—Cr distances to the other carbonyl ligands, as is usual in Fischer carbene complexes (Fischer, 1974).

Data for all three compounds were collected using a profile-fitting method (Clegg, 1981). The crystals of (6) and (8) were cooled using a locally built low-temperature device (Kottke, 1993). The structures were solved by direct methods and refined by full-matrix least-squares methods on *F*². All H atoms were included in calculated positions and refined using a riding model, except the H atoms at N1 of compound (3), which were refined with distance restraints. The isotropic

A Cationic Rhodium–Platinum Complex: *fac*-Tricarbonylrhenium-bis[μ -methylaminobis(difluorophosphine)]-triphenylphosphineplatinum Trifluoromethanesulfonate

JOEL T. MAGUE AND ZHAIWEI LIN

Department of Chemistry, Tulane University,
New Orleans, LA 70118, USA

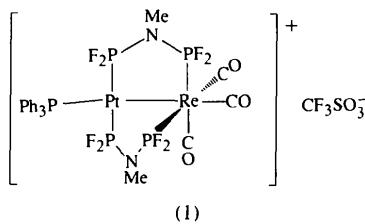

(Received 10 February 1995; accepted 16 May 1995)

Abstract

The title compound, *fac*-tricarbonyl-1 κ^3 C-bis[μ -methylaminobis(difluorophosphine)-1 κP :2 $\kappa P'$]triphenylphosphine-2 κP -platinumrhenium (Pt — Re) trifluoromethanesulfonate, $[PtRe(CO)_3(CH_3F_4NP_2)_2(C_{18}H_{15}P)]\cdot CF_3SO_3^-$, exhibits distorted octahedral and square-planar coordination about the Re and Pt atoms, respectively. A Pt — Re single bond of length 2.818(1) Å is present.

Comment

Previous studies of the ‘metalloligands’ $CpMCl\{\eta^1-\text{MeN}(PF_2)_2\}_2$ ($M = Fe, Ru$) and *fac*- $ReBr(CO)_3(\eta^1-L_2)_2$ [$L_2 = \text{MeN}(PF_2)_2, \text{CH}_2(\text{PMe}_2)_2$ (dmpm)] (Mague & Lin, 1992, 1994; Mague, 1994) have shown them to be useful for the directed synthesis of heterobimetallic complexes. To date, the reactions of these complexes have proven quite limited; in an attempt to increase reactivity, the weakly bound Br ligand in *fac*- $Re(CO)_3\{\mu-\text{MeN}(PF_2)_2\}_2PtBr(PPh_3)$, (2) (Mague & Lin, 1994), was removed by reacting with silver trifluoromethanesulfonate to give the title compound, (1). Little increase in the reactivity of (1) over its precursor was seen, suggesting that the trifluoromethanesulfonate ion might be coordinated in place of the Br atom. As spectroscopic data were inconclusive on this point, the structure of (1) was determined by X-ray analysis.

In the crystal form, (1) consists of well separated $[Re(CO)_3\{\mu-\text{MeN}(PF_2)_2\}_2Pt\{P(C_6H_5)_3\}]^+$ cations and $CF_3SO_3^-$ anions. Both ions have crystallographically imposed mirror symmetry and while the displacement
