# dL-Pheniramine Hydrogen Maleate 

Masood Parvez and Michael Rusiewicz<br>Department of Chemistry, University of Calgary, 2500<br>University Drive NW, Calgary, Alberta, Canada T2N IN4

(Received 22 March 1995; accepted 25 July 1995)

#### Abstract

The structure of the title compound, $N, N$-dimethyl-$\gamma$-phenyl-2-pyridinepropanaminium hydrogen maleate, $\mathrm{C}_{16} \mathrm{H}_{21} \mathrm{~N}_{2}^{+} . \mathrm{C}_{4} \mathrm{H}_{3} \mathrm{O}_{4}^{-}$, a potent anti-allergic drug, is composed of hydrogen-bonded pheniraminium cations and maleate anions, the latter forming a seven-membered ring through an intramolecular hydrogen bond.

## Comment

Continuing our interest in the studies of anti-allergic drugs effective on H1-receptors, we have solved the crystal structure of DL-pheniramine hydrogen maleate, (1). In this paper, we wish to report the result of our analysis and a comparison of the conformation of
(1) with those of its derivatives, DL-brompheniramine
(2) (James \& Williams, 1971), DL-chlorpheniramine (3) (Parvez, 1990) and D-chlorpheniramine (4) (James \& Williams, 1974).

(1)

An ORTEPII (Johnson, 1976) drawing (Fig. 1) shows the hydrogen-bonded structure of the pheniraminium cation and maleate anion with atomic numbering scheme. The molecular dimensions in (1) are normal, with the following average bond distances in the cation: $\mathrm{C}_{s p^{3}}-\mathrm{C}_{s p^{3}} 1.530(9), \mathrm{C}_{s p^{3}}-\mathrm{C}_{s p^{2}} 1.513(9), \mathrm{C}-\mathrm{C}_{\text {aromatic }}$ $1.372(9), \mathrm{N}-\mathrm{C}_{s p^{3}} 1.495(8), \mathrm{N}-\mathrm{C}_{s p^{2}} 1.349$ (19) $\AA$, and in the anion: $\mathrm{C}=\mathrm{O} 1.233(7), \mathrm{C}-\mathrm{O} 1.285(10), \mathrm{C}=\mathrm{C}$ 1.325 (9) and $\mathrm{C}_{s p^{2}}-\mathrm{C}_{s p^{2}} 1.490$ (8) $\AA$. The cation and the anion are hydrogen bonded with an $\mathrm{N} 1 \cdots \mathrm{O} 1$ separation of 2.714 (7) $\AA$ and $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ angle of $165^{\circ}$. The maleate anion, which is essentially planar, forms a seven-membered ring through an intramolecular hydrogen bond with $\mathrm{O} 2 \cdots \mathrm{O} 32.433$ (6) $\AA$ and a linear $\mathrm{O}-$
$\mathrm{H} \cdots \mathrm{O}$ angle $\left(180^{\circ}\right)$. The angles at the $\mathrm{C}_{s p^{2}}$ atoms C 18 and C19 in the anion are much larger than the ideal $120^{\circ}$ value [131.1 (7) and $130.3(7)^{\circ}$, respectively] and are in accordance with the values observed in the maleate anions in the crystal structures of (2), (3) and (4).

Fig. 1. An ORTEPII (Johnson, 1976) drawing showing the intramolecular hydrogen bond between the pheniraminium and maleate ions and the intramolecular hydrogen bond within the maleate anion. The non-H atoms have been plotted as displacement ellipsoids at the $50 \%$ probability level.

A comparison of the conformation of (1) with the conformations of (2), (3) and (4) shows significant differences in the angles between least-squares planes; the conformations of (2) and (3) are somewhat identical. The six-membered rings in (1) are inclined at 92.9 (2) ${ }^{\circ}$ as compared with $76.3(2), 74.9(1)$ and $66.3(2)^{\circ}$ in (2), (3) and (4), respectively. The mean planes of the aminopropyl chain ( $\mathrm{N} 1, \mathrm{C} 6, \mathrm{C} 13, \mathrm{C} 14$ ) and pyridyl rings in (1) and (4) are also inclined at right angles [89.2 (2) and $87.0(2)^{\circ}$, respectively] compared with 34.2 (2) and 37.8 (2) ${ }^{\circ}$ in (2) and (3), respectively. The aminopropyl chain lies almost in the phenyl ring plane [at $12.1(2)^{\circ}$ ] in (1) as opposed to almost at right angles in (2) and (3) [80.2 (2) and $80.1(1)^{\circ}$, respectively] and at $62.5(2)^{\circ}$ in (4). It is interesting to note that the longest fully extended chain in both (1) and (4) is comprised of atoms N1,C5,C6,C13,C14,C16 with C7 and C15 cis with respect to each other and $1.20-1.31 \AA$ out of the least-squares planes of these atoms. On the other hand, in (2) and (3), N1,C6,C7,C13,C14,C16 constitute the longest chain with C5 and C15 cis to each other.

## Experimental

Colourless prismatic crystals of the title compound (Sigma Inc.) were obtained from its solution in ethanol by slow evaporation at room temperature.

The crystals did not diffract well. Even with a large crystal of the approximate dimensions $0.60 \times 0.43 \times 0.35 \mathrm{~mm}$ and collecting data at a temperature of 170 K , only $50 \%$ of the reflections were observed for $\theta=20^{\circ}$ (2100 measured reflections) which dropped further to $20 \%$ in the $\theta$ range of $20-25^{\circ}$, yielding only $1349(40 \%)$ observed data.

The space group was uniquely determined to be $P b c a$ (61) from the systematic absences: $0 k l, k=2 n+1 ; h 0 l, l=2 n+$ 1; $h k 0: h=2 n+1$. H atoms, located from a $\Delta F$ map, were included at geometrically idealized positions with $\mathrm{C}-\mathrm{H}, \mathrm{N}-$ H and $\mathrm{O}-\mathrm{H}=0.95 \AA$.

# Attractive Edge-Face Arene-Arene Interactions in Combination with Close Packing of Alkoxy Chains for 1,4-Didecyloxybenzene 

Huub Koolman, ${ }^{a}$ Anthony L. Spek, ${ }^{a}$ Erik M. D. Keegstra, ${ }^{b}$ Jan W. Zwikker ${ }^{b}$ and Leonardus W. Jenneskens ${ }^{b}$<br>${ }^{a}$ Bijvoet Center for Biomolecular Research, Department of Crystal and Structural Chemistry, Utrecht University, Padualaan 8, 3584 CH Utrecht, The Netherlands, and ${ }^{b}$ Debye Institute, Department of Physical Organic Chemistry, Utrecht University, Padualaan 8, 3584 CH Utrecht, The Netherlands

(Received 20 June 1995; accepted 1 August 1995)

#### Abstract

The crystal structure of 1,4 -didecyloxybenzene, $\mathrm{C}_{26} \mathrm{H}_{46}{ }^{-}$ $\mathrm{O}_{2}$, displays a packing motif which is determined primarily by attractive edge-face arene-arene interactions and is cooperative with the close packing of the alkyl chains. The oblique topology of the benzene moieties is essentially similar to that found for the homologous 1,4-dimethoxy and 1,4-diethoxy derivatives.

## Comment

For many applications of simple $\pi$-conjugated compounds in material science, besides appropriate molecular properties, intermolecular $\pi$-overlap is an additional prerequisite. It is well established that numerous simple planar $\pi$-systems tend to aggregate edge-face in the solid state (Hunter, 1994, and references therein). Nevertheless, the intermolecular organization required for favourable $\pi$-overlap between constituents, i.e. a faceface orientation, may be induced via selective substitu-
tion with either long alkyl or alkoxy chains. Recently, we have shown by comparing solid-state packing motifs of 1,2,4,5-tetramethoxybenzene (herringbone-like; von Deuten \& Klar, 1979) and 1,2,4,5-tetradecyloxybenzene (board-like; Keegstra et al., 1995) that the introduction of the decyloxy chains markedly affects intermolecular interactions and hence intermolecular organization. As expected (Jorgensen \& Severance, 1990, and references therein), no edge-face interactions are discernible in the case of 1,2,4,5-tetramethoxybenzene.

(I)

To gain insight to what extent this observation is affected by the number, length and substitution pattern of alkoxy chains, we decided to determine the single-crystal X -ray structure of 1,4 -didecyloxybenzene. Single-crystal X-ray structures have been reported for the homologous 1,4-dimethoxybenzene (Goodwin, Przybylska \& Robertson, 1950) and 1,4diethoxybenzene (Haisa \& Kashino, 1977). Edge-face interactions play an important role in determining their solid-state packing motif. As can be seen from Fig. 2, 1,4-didecyloxybenzene also possesses a packing motif which is primarily determined by attractive edgeface arene-arene interactions. The acute angle between the least-squares planes through the symmetry-related phenyl rings is $69.1(2)^{\circ}$. The distance between the cen-
