(Received 27 July 1995; accepted 31 October 1995)

Abstract

The title compound, $[Ni(C_3H_6N_4S)_2(H_2O)_2](NO_3)_2$, is an octahedral complex of nickel(II) in which two triazole ligands are coordinated in a bidentate fashion through the amine and thione substituents. The coordination sphere has the two S atoms *trans* with respect to each other, while the N atoms and two water molecules are ligated in *cis* positions. The Ni—S and Ni—N bond lengths in the chelate are consistent with those in similar octahedral nickel complexes. The geometry of the complexed triazole moiety is not substantially different from that of the free molecule.

Comment

Thiosemicarbazones and related compounds with S-C-N linkages display a wide range of biological activity. Metal complexes of these compounds have been synthesized in order to gauge their activity versus that of the free ligand and to determine the coordination behavior of the ligand towards the metal (Offiong, 1995; West, Lockwood, Liberta, Chen & Willett, 1993; Satpathy, Panda, Mishra, Chopdar & Pradhan, 1991). Relatively few complexes of divalent nickel with a chelated S-C-N-N moiety have been structurally characterized. Those that have been characterized include squareplanar, trigonal-bipyramidal and octahedral complexes. Square-planar geometries are observed in the sulfate (Gronbek & Rasmussen, 1962) and nitrate (Hazell, 1972) salts of bis(thiosemicarbazide)nickel(II). Both cis and trans isomers were reported, with no coordination by the anion or water molecules. Acetylpyrazine thiosemicarbazones (West, Lockwood, Liberta, Chen & Willett, 1993) act as tridentate ligands towards Ni, forming square-planar complexes together with a chloro ligand. In all of the square-planar examples, the Ni-S bond distances are in the range 2.16-2.19 Å, while the Ni-N distances are in the range 1.85-1.95 Å. The difference in the Ni-S and Ni-N bond lengths is consistent with the difference in van der Waals radii of S and N atoms (Bondi, 1964). Trigonal-bipyramidal geometries are found in the bis(acetone thiosemicarbazone)chloronickel(II) and bis(acetone thiosemicarbazone)nitratonickel(II) complexes (Mathew, Palenik & Clark, 1973). The N atoms occupy the apical positions and the S atoms the equatorial positions of the trigonal bipyramid. The increase in coordination number is accompanied by an increase in Ni-S [2.290(2)-2.337(5) Å] and Ni-N [2.098 (11)-2.139 (12) Å] distances. The tris-(thiosemicarbazide)nickel(II) complex (Ballard, Powell & Jayasooriya, 1974) is octahedral, with the ligands in a meridional arrangement. The Ni-S bond distances are longer still [2.399(8)-2.432(8)]Å], while the Ni—N distances [2.087(11)-2.114(11)] are similar to those in the pentacoordinate complexes. There appears to be a corresponding shortening of the S-C bond length from square planar [1.712 (5)-1.756 (3) Å] through trigonal bipyramidal [1.65 (2)-1.710 (7) Å] to octahedral [1.69(1)Å], though the changes are small and the errors large in some cases. The metrical data (Table 2) for the title compound, (I), are consistent with this pattern and very similar to those of the other octahedral complex. Though bis(aminomercaptotriazole)diaquanickel(II) complexes have been reported (Satpathy, Panda, Mishra, Chopdar & Pradhan, 1991), the title compound is the first whose structure has been determined.

As shown in Fig. 1, the nearly planar triazole ligands bond to the Ni atom with the S atoms in trans positions and the N atoms in cis positions. The remaining two cis sites are occupied by water molecules. The Ni atom resides on a twofold rotation axis which bisects the O-Ni-O and N-Ni-N bond angles. The crystal packing (Fig. 2) is reinforced by hydrogen bonds between neighboring complexes (O-H···N) and between the complex cation and nitrate ion $(N-H \cdot \cdot \cdot O)$. The metrical data for the complexed triazole are very similar to those of the free ligand (Escobar-Valderrama, Garcia-Tapia, Ramirez-Ortiz, Rosales, Toscano & Valdes-Martinez, 1989). The only bond distance that differs by more than three e.s.d.'s is N(1)—N(2) which is longer in the complex [1.419 (4) Å] than in the free triazole [1.397 (3) Å]. As expected, the angles in the S-C-N-N chelate are

Fig. 1. An ORTEPII diagram (Johnson, 1976) of the title complex showing the atomic labeling scheme. The displacement ellipsoids of the non-H atoms are shown at the 50% probability level.

Fig. 2. An ORTEPII packing diagram (Johnson, 1976) showing hydrogen bonding (narrow lines) between the complex cations and nitrate anions. The view is along the c axis, with the a axis vertical.

contracted a few degrees relative to those of the uncomplexed molecule. The amine H atoms are directed towards the S atom in the free ligand, but away from the S atom in the chelate. In both compounds, the triazole exists as the thione tautomer, *i.e.* the ring N atom is protonated rather than the S atom.

Experimental

The triazole ligand was prepared by heating a mixture of thiocarbohydrazide and excess glacial acetic acid under reflux for 4 h. The slightly yellow solid product separated from the clear solution on standing overnight at room temperature. The triazole and nickel nitrate hexahydrate were combined in a 2:1 molar ratio in warm ethanol, yielding a green solution. Deepgreen crystals of the title compound grew from this solution on standing. Elemental analysis (C, H and N) of the crystals was in excellent agreement with the formula obtained from the X-ray structure analysis.

(Received 17 October 1995; accepted 30 October 1995)

Abstract

The crystal structure of a second polymorph of $[Pd(CH_3)(C_6H_5)(C_{10}H_8N_2)]$, containing four crystallographically independent molecules, is presented and compared with the structure of the previously reported polymorph [Markies *et al.* (1994). *J. Organomet. Chem.* **482**, 191–199] containing only one crystallographically independent molecule. In both polymorphs molecules lie in infinite stacks, surrounded by six similar stacks; the main difference between the two polymorphs is about 23° in the tilt angle of the coordination plane with reference to the stacking direction.

Comment

Preliminary attempts to obtain crystals of the title compound yielded needles [modification (II)] with a large monoclinic unit cell and four molecules per asymmetric unit. Subsequent attempts under essentially the same crystallization conditions yielded better quality monoclinic plates [modification (I)] with one molecule in the asymmetric unit (Markies *et al.*, 1991, 1994). Although less accurate than the previously reported structure [modification (I)], the crystal structure of modification (II) is relevant in view of the current interest in polymorphs (Gavezzotti, 1994; Dunitz & Bernstein, 1995). Polymorphs provide information on conformational flexibility and are relevant for *ab initio* crystal structure predictions (Gavezzotti, 1994).

The four crystallographically independent molecules in (II) (Fig. 1) have very similar conformations that closely resemble the conformation found in (I). The main difference between the five molecules may be
