#### Abstract

The geometry about the Ag atom in the title complex, $\left[\mathrm{AgI}\left(\mathrm{C}_{18} \mathrm{H}_{15} \mathrm{P}\right)_{3}\right]$, is distorted tetrahedral with the $\mathrm{Ag}-\mathrm{I}$ bond length 2.8660 (11) $\AA$ and $\mathrm{Ag}-\mathrm{P}$ distances 2.5335 (14), 2.5589 (12) and 2.6814 (12) $\AA$. The $\mathrm{P}-\mathrm{Ag}-\mathrm{P} / \mathrm{I}$ angles show large variations [104.54(3)$116.10(4)^{\circ}$ ] from the ideal tetrahedral value ( $109.45^{\circ}$ ).

These distortions, as well as those around the P atoms in the three triphenylphosphine ligands, may be attributed to several intramolecular ( $\mathrm{H} \cdots \mathrm{I}$ and $\mathrm{H} \cdots \mathrm{C} / \mathrm{H}$ ) short contacts.

## Comment

A number of tris(triphenylphosphine)silver(I) derivatives of the type $\left[\mathrm{Ag}\left(\mathrm{PPh}_{3}\right)_{3} X\right]$ have been characterized by X-ray crystallography: $X=\mathrm{Cl}$ (Cassel, 1981), $X=\mathrm{Cl}, \mathrm{Br}$ or I (Englehardt, Healy, Patrick \& White, 1987), $X=\mathrm{I}, \mathrm{BF}_{4}$ (Camalli \& Caruso, 1987), and $X=\mathrm{NO}_{3}$ (Barron et al., 1986; Bruce \& Duffy, 1986). All these complexes are molecular species, in each of which the Ag atom has distorted tetrahedral geometry. The nitrate derivative is monoclinic and isostructural with the room-temperature (RT) iodide structure reported by Englehardt et al. (1987), with the N atom of the bidentate nitrate group occupying almost the same position as the $I$ atom. In the $\mathrm{BF}_{4}$ complex there is one $\mathrm{Ag}-\mathrm{F}$ interaction which is long [2.82 (1) $\AA$ ], but it definitely indicates a bonding (albeit weak) interaction. The RT iodide structure reported

(I)
by Englehardt et al. (1987) is monoclinic with one long and two short $\mathrm{Ag}-\mathrm{P}$ bonds [2.780 (3), 2.544 (2) and 2.573 (3) $\AA$ ] , while the structure reported by Camalli \& Caruso (1987) is triclinic with the Ag-P bonds falling within a narrow range $[2.572(4)-2.616(3) \AA]$. We undertook an X-ray study of the complex at 140 K (low temperature, LT) to obtain more accurate data and confirm the unusual variations in the reported molecular geometry parameters. The LT structure reported here (Fig. 1) is isostructural with the RT monoclinic form reported by Englehardt et al. (1987).

The $\mathrm{Ag}^{\mathrm{I}}$ centre is tetrahedral with one $\mathrm{Ag}-\mathrm{P}$ bond [2.6814 (12) $\AA$ ] much longer than the other two [ 2.5335 (14) and 2.5589 (12) $\AA$ ]. These values follow the trend observed in the RT monoclinic structure (Englehardt et al., 1987), but in the latter case the longest $\mathrm{Ag}-\mathrm{P}$ bond is $c a 0.10 \AA$ longer than the corresponding value in our structure. The situation is somewhat dif-

[^0]

Fig. 1. Structure of $\left[\mathrm{Ag}\left(\mathrm{PPh}_{3}\right) I\right]$ showing the atom-numbering scheme (C336 is obscured by C312). Displacement ellipsoids are drawn at the $50 \%$ probability level. H atoms, represented by small circles of arbitrary radii, have the same numbers as their parents.
ferent in the triclinic form (Camalli \& Curso, 1987) in which all the $\mathrm{Ag}-\mathrm{P}$ distances fall within a narrow range [ $2.572(4)-2.616$ (3) A $\AA$ ]. The average value for the $\mathrm{Ag}-\mathrm{P}$ bond in the present structure ( $2.591 \AA$ ) compares very well with that in the triclinic form ( $2.596 \AA$ ), but is ca $0.04 \AA$ shorter than in the RT monoclinic structure ( $2.632 \AA$; Englehardt et al., 1987). It is also noted that the $\mathrm{Ag}-\mathrm{P}$ distances in all three iodide structures are markedly longer than those in the nitrate [2.525 (1)-2.630 (2), average $2.567 \AA$ (Barron et al., 1986); 2.522 (3)-2.630(3), average $2.568 \AA$ (Bruce \& Duffy, 1986)], chloride [2.520(1)-2.552 (1), average $2.543 \AA$ (Cassel, 1981); 2.558 (5)-2.582 (4), average $2.572 \AA$ (Englehardt et al., 1987)] and bromide $[2.528$ (3)- 2.549 (7), average $2.536 \AA$ (Englehardt et al., 1987)] derivatives. The Ag-I distance of $2.8660(11) \AA$ is very similar to those in the RT monoclinic [2.856 (1) Å (Englehardt et al., 1987)] and triclinic [2.655 (1) and 2.864 (1) $\AA$ (Camalli \& Curso, 1987)] forms.

The P - $\mathrm{Ag}-\mathrm{I}$ and $\mathrm{P}-\mathrm{Ag}-\mathrm{P}$ angles lie in the ranges $104.54(3)-107.86(3)^{\circ}$ (average $106.0^{\circ}$ ) and $107.91(4)-116.10(4)^{\circ}$ (average $112.6^{\circ}$ ), respectively. These values are comparable with the corresponding angles [104.03(6)-109.00(6), average $106.7^{\circ} ; 107.00(7)-$ 116.93 (7), average $112.0^{\circ}$ ] in the RT monoclinic structure (Englehardt et al., 1987), and in both cases the two shorter $\mathrm{Ag}-\mathrm{P}$ bonds subtend the largest P -$\mathrm{Ag}-\mathrm{P}$ angle. In the triclinic form, the $\mathrm{P}-\mathrm{Ag}-\mathrm{I}$ and P -Ag- P angles lie in the ranges 103.8 (1)$109.0(1)^{\circ}$ (average $105.6^{\circ}$ ) and $110.8(1)-114.1(1)^{\circ}$ (average $112.9^{\circ}$ ), respectively, the latter showing less variation than those in both the monoclinic structures.

The variations from ideal values ( $109.4^{\circ}$ ) are consistent with the 'tetrahedral' coordination about the $\mathrm{Ag}^{1}$ centre being trigonally distorted, with the iodo ligand 'axial', and may be explained by the presence of several intramolecular $\mathrm{I} \cdots \mathrm{H}$ short contacts $[\mathrm{I} \cdots \mathrm{H} 122=$ $3.17, \mathrm{I} \cdots \mathrm{H} 212=3.14, \mathrm{I} \cdots \mathrm{H} 312=3.24 \AA$ A. The $\mathrm{P}-\mathrm{C}$ bond lengths vary from 1.814 (4) to 1.846 (4) A (average $1.831 \AA$ ), which are comparable with those in other related structures. The bond angles at the three P atoms display wide variations with $\mathrm{C}-\mathrm{P}-\mathrm{C}$ angles ranging from 100.6 (2) to 105.8 (2) ${ }^{\circ}$ and $\mathrm{Ag}-\mathrm{P}-\mathrm{C}$ angles ranging from 108.7 (1) to $123.6(1)^{\circ}$. The large variations in the $\mathrm{Ag}-\mathrm{P}-\mathrm{C}$ angles are explained by several intramolecular short contacts between different $\mathrm{PPh}_{3}$ ligands, the most important of these interactions being $\mathrm{C} 122 \cdots \mathrm{H} 312=2.70, \mathrm{H} 132 \cdots \mathrm{C} 332=2.73$ and $\mathrm{H} 222 \cdots \mathrm{C} 322=2.78 \AA$. The orientations of the three $\mathrm{PPh}_{3}$ ligands are the same as in the RT structure with one ligand adopting a skew and two adopting staggered conformations (Englehardt et al., 1987).

The present structure is also very similar to those reported for the triclinic and trigonal forms of $\mathrm{CuI}\left(\mathrm{PPh}_{3}\right)_{3}$, in which the average $\mathrm{P}-\mathrm{Cu}-\mathrm{P}$ angles are 115.0 and $110.3^{\circ}$, respectively, and the $\mathrm{Cu}-X(X=\mathrm{I}, \mathrm{P})$ distances are ca $0.20 \AA$ Ahorter (Barron et al., 1987). It was suggested that the overall geometry of the tetrahedral $\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{3} \mathrm{CuX}$ core including the unequal $\mathrm{Cu}-\mathrm{P}$ distances $[2.327$ (2)-2.362 (3) $\AA$ ] is significantly influenced by several intramolecular $\mathrm{H} \cdots \mathrm{C} / \mathrm{H}$ and $\mathrm{H} \cdots X$ short contacts, which also affect the conformational changes within the $\mathrm{PPh}_{3}$ ligands. This explanation seems equally suited to the Ag case where close $\mathrm{I} \cdots \mathrm{H}$ and $\mathrm{H} \cdots \mathrm{C} / \mathrm{H}$ contacts are again apparent.

## Experimental

The compound was prepared as colourless crystals, m.p. 446447 K (lit. m.p. 438-443 K; Englehardt et al., 1987) in a manner described for the chloride analogue (Cassel, 1981) by substituting [ $\left.{ }^{n} \mathrm{Bu}_{4} \mathrm{~N}\right] I$ for $\left[\mathrm{Et}_{4} \mathrm{~N}\right] \mathrm{Cl}$. Suitable single crystals were grown from a chloroform solution of the complex layered with hexane and left undisturbed overnight. IR bands ( KBr , $\left.\mathrm{cm}^{-1}\right) 3048,1584,1478(m), 1310,1155,1091(m), 1025$, 997, 854, 743(s), 694(s), 512(s). ${ }^{31} \mathrm{P}$ NMR (RT, CDCl 3 ): $\delta=$ -1.18 p.p.m., relative to $\mathrm{H}_{3} \mathrm{PO}_{4}$.

H atoms were included in calculated positions (riding model, $\mathrm{C}-\mathrm{H}=0.93 \AA$ ) with $U_{\text {iso }}$ set at $1.2 \times U_{\mathrm{cq}}$ of the parent C atom. Highest residual electron densities in the final difference map which lie close to the Ag and I atoms are devoid of any stereochemical significance.
Data collection: MADNES (Pflugrath \& Messerschmidt, 1989); further details from Darr, Drake, Hursthouse \& Malik (1993). Cell refinement: REFINE in MADNES. Data reduction: ABSMAD (Karaulov, 1992). Program(s) used to solve structure: SHELXS86 (Sheldrick, 1985). Program(s) used to refine structure: SHELXL93 (Sheldrick, 1993). Molecular graphics: SNOOPI (Davies, 1983). Software used to prepare material for publication: SHELXL93.

## Abstract

The structure of the title compound, $\left[\mathrm{Cu}_{4}\left(\mathrm{~S}_{5}\right)_{2}\left(\mathrm{C}_{6} \mathrm{H}_{7}-\right.\right.$ $\left.\mathrm{N})_{4}\right] .2 \mathrm{C}_{6} \mathrm{H}_{7} \mathrm{~N}$, consists of a neutral complex molecule $\left[\mathrm{Cu}_{4}\left(\mathrm{~S}_{5}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{C}_{5} \mathrm{H}_{4} \mathrm{~N}\right)_{4}\right]$ and two 3-methylpyridine solvent molecules. In the neutral complex molecule, the four Cu atoms are in a distorted tetrahedral arrangement. The non-bonding $\mathrm{Cu} \cdots \mathrm{Cu}$ distances in the copper tetrahedron range from 3.281 (1) to 3.948 (1) $\AA$ and the $\mathrm{Cu}-\mathrm{S}$ bond lengths vary from 2.255 (2) to 2.397 (3) $\AA$.

## Comment

In recent years, since remarkably rich photoluminescence has been found in tetranuclear complexes (Kevin,

Chong, John \& Peter, 1991) and the cage-type structure with $\mu_{3}$-S may be potentially used in optical-limiting material (Shi, Ji, Tang, Lang \& Xin, 1994), the synthesis of tetranuclear copper(I)-sulfur clusters has attracted attention. To date, a series of tetranuclear copper(I) clusters have been studied (Hathaway, 1987). Herein, a new tetranuclear copper(I) compound, namely, $\left[\mathrm{Cu}_{4}\left(\mathrm{~S}_{5}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{C}_{5} \mathrm{H}_{4} \mathrm{~N}\right)_{4}\right] .2 \mathrm{CH}_{3} \mathrm{C}_{5} \mathrm{H}_{4} \mathrm{~N}$, (I), is reported.

(I) (MePy = 2-methylpyridine)

The structure of the neutral complex molecule of the title compound is shown in Fig. 1. The neutral molecule is located on a twofold axis which passes through atoms $S(3)$ and $S(6)$. Each Cu atom has distorted tetrahedral geometry and is coordinated by three $\mu_{3}$-S atoms and an N atom from the pyridine ligand. The four Cu atoms are held together by two pentasulfido $\mathrm{S}_{5}^{2-}$ groups acting as bridging and chelating ligands.

Fig. 1. ORTEPII view (Johnson, 1976) of the title compound. Displacement ellipsoids are shown at the $50 \%$ probability level.

In the title compound, the four non-bonding $\mathrm{Cu} \cdots \mathrm{Cu}$ distances are $3.948(1)\left[\mathrm{Cu}(1) \cdots \mathrm{Cu}\left(1^{\prime}\right)\right]$, $3.312(2)[\mathrm{Cu}(1) \cdots \mathrm{Cu}(2)], 3.281(1)\left[\mathrm{Cu}(2) \cdots \mathrm{Cu}\left(1^{\prime}\right)\right]$ and $3.945(1) \AA\left[\mathrm{Cu}(2) \cdots \mathrm{Cu}\left(2^{\prime}\right)\right]$. The $\mathrm{Cu}-\mathrm{S}$ bond lengths vary from 2.255 (2) to 2.397 (3) $\AA$. The S-S bond lengths in the two $\mathrm{S}_{5}^{2-}$ ions vary from 2.062 (3) to 2.076 (5) $\AA$. These distances are close to those found
