## Abstract

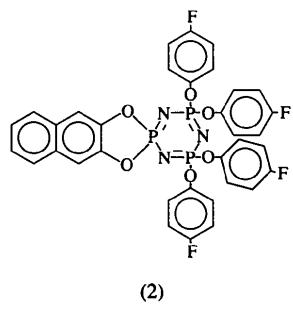

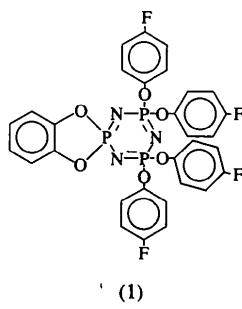

The reactions of  $p$ -FC<sub>6</sub>H<sub>4</sub>OSiMe<sub>3</sub> with N<sub>3</sub>P<sub>3</sub>F<sub>4</sub>X [where X is either 1,2-O<sub>2</sub>C<sub>6</sub>H<sub>4</sub> or 2,3-O<sub>2</sub>C<sub>10</sub>H<sub>6</sub>] provide a convenient route to fully substituted phosphazenes, N<sub>3</sub>P<sub>3</sub>(*p*-FC<sub>6</sub>H<sub>4</sub>O)<sub>4</sub>X. The X-ray structures of the monospiro phosphazene derivatives of 1,2-benzenedioyl [4,4,6,6-tetrakis(4-fluorophenoxy)-2,2-(1,2-phenylenedioxy)-1,3,5,2,4,6-cyclophosphazene, (1), C<sub>30</sub>H<sub>20</sub>F<sub>4</sub>N<sub>3</sub>O<sub>6</sub>P<sub>3</sub>] and 2,3-naphthalenedioyl [4,4,6,6-tetrakis(4-fluorophenoxy)-2,2-(1,2-naphthalenedioxy)-1,3,5,2,4,6-cyclophosphazene, (2), C<sub>34</sub>H<sub>22</sub>F<sub>4</sub>N<sub>3</sub>O<sub>6</sub>P<sub>3</sub>] contain an almost planar N<sub>3</sub>P<sub>3</sub> core which lies perpendicular to the planar five-membered spiro group. The F atoms of the phenoxy groups are involved in the for-

mation of weak intermolecular hydrogen bonds giving rise to dimeric networks in (1) and three-dimensional networks in (2).

### Comment

A large number of structural investigations has been carried out on cyclic phosphazenes containing an aromatic spirocyclic substituent (Chandrasekhar, Murlidharan & Selvraj, 1990). All of the structures that involve the 1,2-benzenediol and 2,3-naphthalenediol groups contain only a trispirophosphazene moiety. These compounds are known to form channel-type clathrates with a variety of guest molecules, namely aromatic and aliphatic hydrocarbons, halocarbons, nitriles, esters, ketones, water,  $CS_2$ , etc. (Allcock, 1984). The structures of tris(1,2-phenylenedioxy)cyclotriphosphazene (TPDOCTP) with benzene, *o*- and *p*-xylene, mesitylene (Allcock, 1984) and water (Allcock, Levine & Whittle, 1986), and of tris(2,3-naphthalenedioxy)cyclotriphosphazene (TNDOCTP) with benzene (Allcock & Stein, 1974), *p*-xylene (Kubono, Asaka, Isoda, Kobayashi & Taga, 1993) and *p*-chlorotoluene (Kubono, Asaka, Taga, Isoda & Kobayashi, 1994) have been reported. Recently, the X-ray structures of guest-free TPDOCTP (Allcock, Levine & Whittle, 1986) and TNDOCTP (Kubono, Asaka, Isoda, Kobayashi & Taga, 1994) have been elucidated.

The synthesis of monospiro 1,2-phenylenedioxycyclophosphazene has been problematic owing to degradation of the reaction products (Allcock & Kugel, 1966). A synthetic methodology involving 1,2-bis(trimethylsilyl)benzenediol and excess  $N_3P_3F_6$  affords the first examples of structurally characterized fluorocyclophosphazenes, *i.e.* monospiro  $N_3P_3F_4(1,2-O_2C_6H_4)$  (3), dispiro  $N_3P_3F_2(1,2-O_2C_6H_4)_2$  (4) and monospiro  $N_3P_3F_4(2,3-O_2C_{10}H_6)$  (5) (Vij, Geib, Kirchmeier & Shreeve, 1996). We present here the structure determinations of 4,4,6,6-tetrakis(4-fluorophenoxy)-2,2-(1,2-phenylenedioxy)-1,3,5,2,4,6-cyclophosphazene, (1), and 4,4,6,6-tetrakis(4-fluorophenoxy)-2,2-(1,2-naphthalenedioxy)-1,3,5,2,4,6-cyclophosphazene, (2).

The displacement ellipsoid plot with the atomic numbering scheme for (1) is shown in Fig. 1. Analysis of the structural data shows that unlike in the parent

compound (3), the  $N_3P_3$  core is distorted from perfect planarity. The N1 and P1 atoms show maximum deviations of  $-0.055(1)$  and  $0.060(1)\text{\AA}$ , respectively, from the r.m.s. deviation of  $0.041\text{\AA}$  for the  $N_3P_3$  core; this is greater than that found in compound (4) [r.m.s. deviation  $0.0145$ , N1  $0.0208$  and P1  $0.0294\text{\AA}$ ]. The remaining atoms in compound (1), N2, P2, N3 and P3, deviate by  $0.042(1)$ ,  $0.003(1)$ ,  $-0.015(1)$  and  $-0.036(1)\text{\AA}$ , respectively. The five-membered spirocyclic  $PO_2C_2$  ring lies roughly perpendicular to the  $N_3P_3$  ring [ $88.6(1)^\circ$ ] and is slightly bent at the O atoms as is evident from the torsion angle values of  $3.0(3)^\circ$  for P1—O1—C1—C2 and  $-4.6(3)^\circ$  for P1—O2—C2—C1. Compound (3) belongs to the *Imma* space group, with atoms P1 and N1 lying at the intersection of two mirror planes which results in a planar  $PO_2C_2$  ring. The distortion of the 1,2-phenylenedioxy groups at the O atoms appears to be a function of the number of spirocyclic groups on the  $N_3P_3$  ring. In compound (4), which contains two spiro groups, the  $PO_2C_2$  rings show greater P—O—C—C torsion-angle values of  $4.1(4)$  and  $-5.9(4)^\circ$  at P1, and  $5.9(5)$  and  $-6.5(5)^\circ$  at P2, whereas in trispiro  $N_3P_3(1,2-O_2C_6H_4)_3$  (Allcock, Levine & Whittle, 1986), the average values are even greater at  $\sim 7$ ,  $\sim 14$  and  $\sim 15^\circ$ .

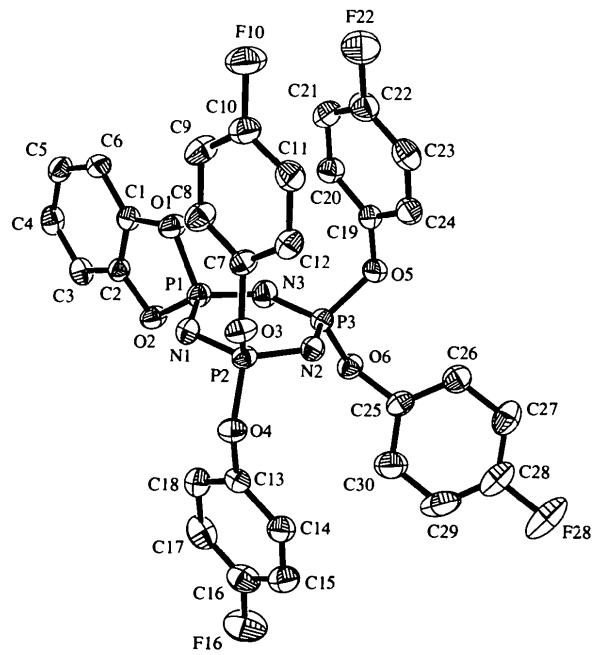

Fig. 1. The molecular structure of compound (1) showing the labeling scheme and 50% probability displacement ellipsoids.

In the case of  $N_3P_3(p-FC_6H_4O)_6$ , the aryl rings are stacked roughly perpendicular to the  $N_3P_3$  ring. For compound (1), the mean planes of the fluoroaryloxy and  $N_3P_3$  rings make dihedral angles of  $90.0(1)$  for C7—C12 and  $101.5(1)^\circ$  for C13—C18 (bonded to P2),

and 104.3 (1) for C19–C24 and 63.0 (1) $^\circ$  for C25–C30 (bonded to P3). These values are greater than those found in  $\text{N}_3\text{P}_3(2,2'\text{-O}_2\text{C}_{12}\text{H}_8)(p\text{-FC}_6\text{H}_4)_4$  (Vij, Geib, Kirchmeier & Shreeve, 1996) owing to the presence of the less sterically demanding (*vis-à-vis* 2,2'-biphenoxy) 1,2-phenylenedioxy group. The conformations of the fluoroaryloxy rings on P2 and P3 are seen from the torsion angles C7–O3–P2–O4 –175.1 (2), C13–O4–P2–O3 –172.2 (2), C19–O5–P3–O6 –177.5 (2) and C25–O6–P3–O5 70.0 (2) $^\circ$ . This difference in stacking behavior results in a mean-plane angle between rings C7–C12 and C13–C18 of 11.7 (1) $^\circ$  *versus* a mean-plane angle between rings C19–C24 and C25–C30 of 52.1 (1) $^\circ$ . The packing diagram of (1) (Fig. 2) shows the longest intermolecular contact, H3...F28<sup>i</sup> [symmetry code: (i) 1 – $x$ , 1 – $y$ , 1 – $z$ ] of 2.64 (3)  $\text{\AA}$ , resulting in dimer formation.

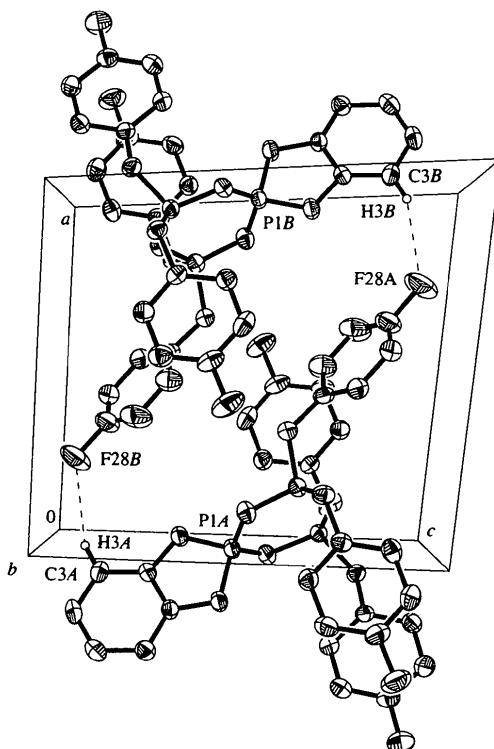

Fig. 2. Drawing of the packing of (1) showing the H...F interactions within the cell.

The molecular structure of compound (2) is shown in Fig. 3. Replacement of the 1,2-phenylenedioxy group in (1) with the 2,3-naphthalenedioxy group results in a lower distortion of the  $\text{N}_3\text{P}_3$  ring. The maximum deviation occurs for the N1 and P2 atoms, with values of –0.019 (1) and 0.023 (1)  $\text{\AA}$ , respectively. The r.m.s. deviation of the  $\text{N}_3\text{P}_3$  ring (0.014  $\text{\AA}$ ) is less than that found in both compound (5) (0.0353  $\text{\AA}$ ) and guest-free TNDOCTP (Kubono, Asaka, Isoda, Kobayashi & Taga,

1994). The naphthalene group is approximately planar [maximum deviation for atom C6 is 0.010 (3)  $\text{\AA}$ ] and lies nearly perpendicular to the  $\text{N}_3\text{P}_3$  group [89.2 (1) $^\circ$ ]. The five-membered spirocycle is slightly bent at the O atoms, as seen from the torsion angles P1–O1–C2–C3 –1.9 (3) and P1–O2–C3–C2 1.4 (3) $^\circ$ . As a consequence, there is some diversity in the C–C bond

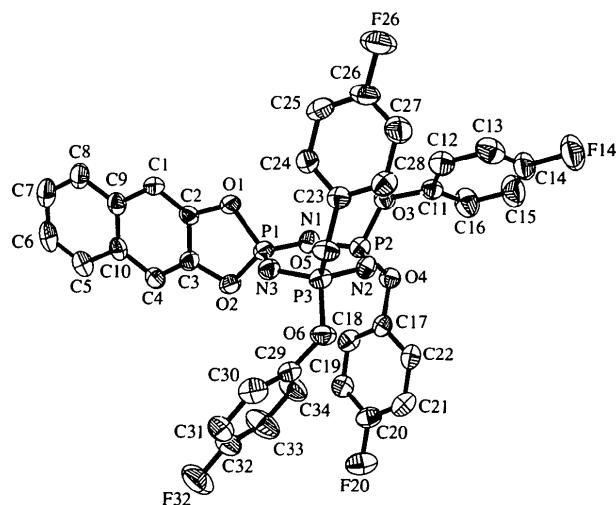

Fig. 3. The molecular structure of compound (2) showing the labeling scheme and 50% probability displacement ellipsoids.

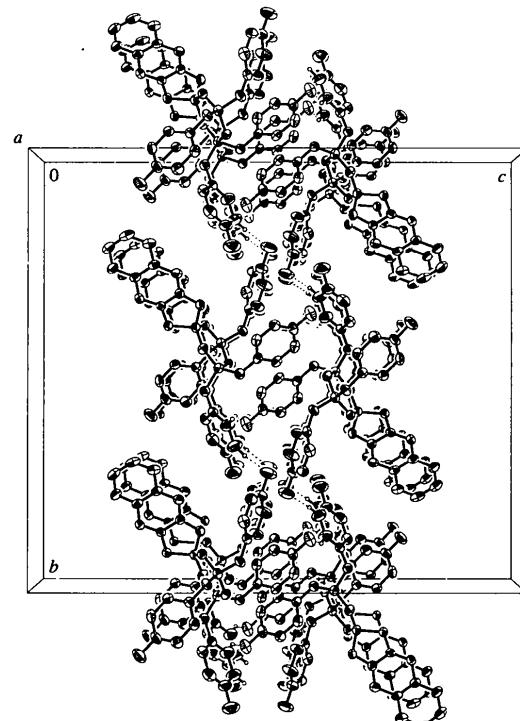

Fig. 4. Drawing of the packing of (2) showing the H...F interactions within the cell.

lengths in the naphthalene ring, *i.e.* C1—C2 1.346 (4) and C1—C9 1.429 (4) Å. Both the magnitude of ring bending and the bond-length diversity, however, are lower than in TNDOCTP, where the torsion angles vary from 8.4 (6) to 18.6 (6)° and the naphthalene bond lengths vary from 1.320 (8) to 1.448 (9) Å (Kubono, Asaka, Isoda, Kobayashi & Taga, 1994). The *p*-fluoro-phenoxy rings are stacked in a more ordered manner compared with compound (1), and the relative dihedral angles between the mean planes of the  $N_3P_3$  ring and the aryl groups are 47.5 (1) for C11—C16 and 106.6 (1)° for C17—C22 (bonded to P2), and 108.3 (1) for C23—C28 and 58.6 (1)° for C29—C34 (bonded to P3). The *p*-fluoroaryloxy rings are twisted with respect to one another, with an angle of 74.9 (1)° for those on atom P2 and 94.0 (1)° for those on atom P3. Two long-range intermolecular interactions, *i.e.* H15···F32<sup>ii</sup> of 2.39 (5) and H16···F20<sup>iii</sup> of 2.46 (4) Å [symmetry codes: (ii)  $\frac{3}{2}-x, -\frac{1}{2}+y, z$ ; (iii)  $2-x, -y, 1-z$ ], are observed in the crystal packing of compound (2) leading to a three-dimensional network (Fig. 4).

## Experimental

Compounds (1) and (2) were prepared by the reaction of  $N_3P_3F_4X_2$  ( $X = 1,2-O_2C_6H_4$  and  $2,3-O_2C_{10}H_6$ , respectively) with a slight excess of *p*-FC<sub>6</sub>H<sub>4</sub>OSiMe<sub>3</sub> in tetrahydrofuran at ~353 K using CsF as catalyst. Removal of the solvent and excess siloxane at ~373 K/0.03 Torr overnight, followed by extraction in chloroform and recrystallization from a chloroform/cyclohexane mixture afforded the desired products. The EI/MS analyses of compounds (1) and (2) show the  $M^+$  peaks as the highest peaks with *m/e* values of 687 and 737, with intensities of 41 and 47%, respectively. The base peak corresponds to the ( $M-O_2C_6H_4F$ )<sup>+</sup> fragment. The multinuclear NMR spectral data are described elsewhere (Vij, Geib, Kirchmeier & Shreeve, 1996).

The diffraction data were collected on a Siemens three-circle diffractometer ( $\chi$  axis fixed at  $54.74^\circ$ ) equipped with a CCD detector maintained at 218.6 K, using the  $\omega$ -scan technique (Campana, Shepard & Litchman, 1980). The initial cell constants were determined from reflection data obtained by collecting  $60 \times 10$  s frames at a detector resolution of  $512 \times 512$  pixels. The final unit-cell values, however, are based on the least-squares refinement of all the observed reflections [4645 for (1) and 3449 for (2)]. A complete hemisphere of data was scanned on  $\omega$  ( $0.3^\circ$ ), with a run time of 10 s frames for a total of 1271 frames collected in three sets plus a final set of 50 frames using the SMART Software (Siemens, 1995c). The crystal decay was monitored through reflection data from 50 frames collected at the beginning and at the end of data collection. The data reduction was accomplished by processing the frames data using SAINT Software (Siemens, 1995a) to give the raw file corrected for  $L_p$  and decay. Since the raw file contains information about directional cosines, it was used for empirical absorption correction. The structures were solved by direct methods using SHELXS86 (Sheldrick, 1990) in SHELXTL-Plus (Siemens, 1995b) and refined by full-matrix least-squares methods using SHELXTL-Plus and SHELXL93 (Sheldrick, 1993). H atoms were located from difference Fourier syntheses and refined with isotropic displacement parameters. All computations were performed on a Silicon Graphics workstation.

The authors are grateful to the National Science Foundation (CHE-9003509) for support of this research. The single crystal CCD X-ray facility at the University of Idaho was established with the assistance of NSF-Idaho EPSCoR program under NSF OSR-9350539 and the M. J. Murdock Charitable Trust, Vancouver, Washington, USA.

Lists of structure factors, anisotropic displacement parameters, H-atom coordinates, complete geometry, and torsion angles have been deposited with the IUCr (Reference: FG1172). Copies may be obtained through The Managing Editor, International Union of Crystallography, 5 Abbey Square, Chester CH1 2HU, England.

## Abstract

Pyridine-2,6-dimethanol,  $C_7H_9NO_2$ , forms a chain structure in which the molecules are linked by  $O—H\cdots O$  hydrogen bonds into dimeric units lying across centres of inversion, these dimers being linked by  $O—H\cdots N$  hydrogen bonds into chains around other centres of inversion. In the structure of benzene-1,3,5-trimethanol,  $C_9H_{12}O_3$ , the molecules form a continuous three-dimensional network in which each molecule is hydrogen-bonded to six others.
