An attempt was made to perform an absorption correction based on ψ scans, but the weak diffraction caused too few suitable reflections to be available. Accordingly, recourse to a ΔF correction had to be made. The transmission factors are somewhat higher than expected. The number of least-squares parameters was artificially increased by 18 to allow for the extra (hidden) parameters introduced. The structure was refined as a racemic twin with components 0.67, 0.33 (11); the origin was fixed by the method of Flack & Schwarzenbach (1988). The high R values are associated with broad reflection profiles, weak diffraction from a thin plate and (probably) residual absorption errors. To improve the refinement stability, a system of restraints (695 in all) to light-atom temperature-factor components and local Cp-ring symmetry was employed.

Abstract

In heptaaquacalcium bis[1,3,2-benzodithiazole 1,1,3,3-tetraoxide(1–)], $[\text{Ca}(\text{H}_2\text{O})_7](\text{C}_6\text{H}_4\text{NO}_4\text{S}_2)_2$, the calcium ion is surrounded by the O atoms of seven water molecules in a distorted pentagonal bipyramidal geometry. The structure displays layers of anions, with the calcium cations and water molecules between these layers. The layers are held together by an extensive network of hydrogen bonds involving the water molecules and the $(\text{SO}_2)_2\text{N}^-$ subunits of the anions.

Comment

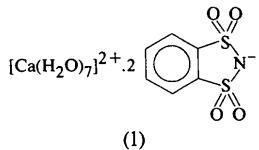

Calcium ions in crystal structures generally bind to O atoms in ligands and their preferred coordination numbers range from 6 to 8 (Katz, Glusker, Beebe & Bock, 1996). However, in hydrated compounds containing six or more water molecules per calcium ion, exclusive hydration of the metal to form $[\text{Ca}(\text{H}_2\text{O})_n]^{2+}$ ($n \geq 6$) is rare; in most of these compounds, the coordination polyhedra involve ligands other than water molecules. It was shown by *ab initio* molecular orbital calculations *in vacuo* that the net energy penalty for changing the number of water molecules in the first coordination shell of Ca^{2+} between 6 and 8 is extremely small (Katz *et al.*, 1996).

The heptahydrated calcium ion has been observed in $\text{CaCr}_2\text{O}_7 \cdot 2[(\text{CH}_2)_6\text{N}_4] \cdot 7\text{H}_2\text{O}$ (Dahan, 1975),

† Part LXXXII: Dalluhn, Henschel, Blaschette & Jones (1997).

in Ca[Bi(edta)]₂.9H₂O (Shkol'nikova, Porai-Koshits & Poznyak, 1993) and in a number of inorganic structures (*e.g.* Thomas & Moore, 1981; Leligny & Monier, 1983; Takagi, Mathew & Brown, 1984; Thiele, Rotter & Faller, 1984; Faggiani, Villella & Brown, 1986). On the other hand, a search of the Cambridge Structural Database (Allen & Kennard, 1993) located only two structures displaying [Ca(H₂O)₇]²⁺ associated with a purely organic counterion, *viz.* Ca(naphthionate)₂.8H₂O (Brown, Ehrenberg & Yadav, 1984), and CaA.9H₂O, where H₂A is 7-hydroxy-8-(phenylazo)-1,3-naphthalene-disulfonic acid (Ojala *et al.*, 1994). It is interesting that these compounds both contain arene-sulfonate anions, which are obviously suited for stabilizing the heptaaquacalcium complex by incorporation into an extended hydrogen-bond network. It should be noted, however, that in the closely related compound [Ca(HA)(H₂O)₆](HA).6H₂O, where H₂A is *o*-tolidine-6,6'-disulfonic acid, Ca²⁺ attains the coordination number seven by bonding to six water molecules and one sulfonate O atom of an anion (Gunderman & Squatrito, 1996). We now report the first structure exhibiting a [Ca(H₂O)₇]²⁺ cation stabilized by a disulfonimide anion.

The asymmetric unit (Fig. 1) of the title compound, (1), consists of one [Ca(H₂O)₇]²⁺ cation and two 1,2-benzenedisulfonimide anions, henceforth denoted as Z⁻ and Z'⁻ (Z⁻ referring to the lower-numbered anion).

The calcium coordination is sevenfold, the O atoms forming a severely distorted pentagonal bipyramidal with a mean Ca—O distance of 2.391 (3) Å (individual values *cf.* Table 1). The apices are occupied by O1w and O5w, with the angle O1w—Ca—O5w 163.57 (12)°. The equatorial atoms are O2w, O3w, O7w, O4w and O6w, subtending angles at Ca of 72.64 (12), 72.81 (11), 75.25 (12), 81.85 (13) and 73.83 (12)°, respectively, a total of 376.38° compared with 360° expected for exact coplanarity of the Ca and five O atoms. The mean deviation of the six atoms from their least-squares plane is 0.47 Å, the largest deviation pertaining to O3w [0.760 (2) Å] and the smallest to Ca [0.057 (1) Å].

The independent anions are almost identical as regards their bond lengths and interbond angles. Selected geometric data for the five-membered ring of Z⁻ are given in Table 1. Including both anions, the C—C distances range from 1.368 (5) to 1.391 (5) Å and the C—C—C angles from 117.3 (3) to 121.9 (3)°. In Z⁻ and Z'⁻, the C and S atoms are effectively coplanar, the greatest deviations from their mean planes and their mean out-of-plane distances being 0.024 (1) and 0.015 Å

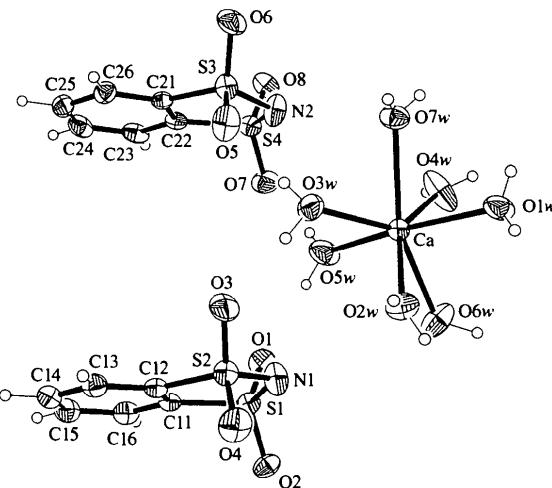

Fig. 1. The formula unit of the title compound in the crystal. Ellipsoids represent 50% probability levels and H-atom radii are arbitrary.

for Z⁻, and 0.009 (3) and 0.005 Å for Z'⁻; N1 and N2 are 0.149 (3) and 0.131 (4) Å out of the reference plane as defined above. The anion was previously characterized in the structure of [(CH₃)₂Sn(H₂O)₄]²⁺.2Z⁻, where it forms interionic hydrogen bonds (Hippler, Jones & Blaschette, 1993), and in the coordination compounds [AgZ(CH₃CN)] (Blaschette *et al.*, 1993) and [AgZ(H₂O)] (Jones, Hamann, Blaschette, Cammenga & Epple, 1993).

As shown in the packing diagram (Fig. 2), the anions are stacked in double layers in which half have the (SO₂)₂N⁻ groups directed towards the next layer up and half towards the layer below. The dihedral angle between the mean C₆S₂ planes of Z⁻ and Z'⁻ is only 4.88 (4)°. Surrounding and connecting the hydrophobic regions are hydrophilic layers composed of water molecules and cations. The (SO₂)₂N⁻ groups of the anions project into the polar regions. Similar stackings were observed for the calcium sulfonate hydrates mentioned

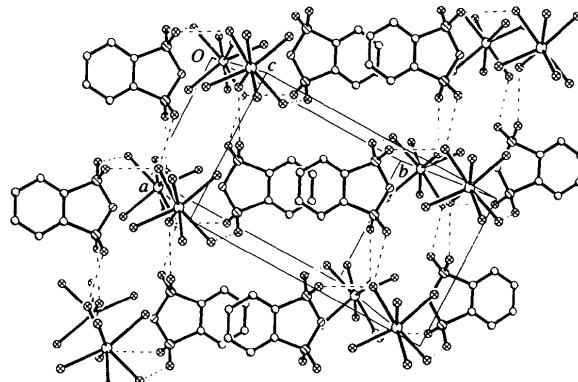

Fig. 2. Packing diagram of the title compound viewed perpendicular to the ab plane. Hydrogen bonds are indicated by dashed lines and H atoms have been omitted for clarity.

above. The structure is extensively hydrogen bonded (Table 2). There are 15 independent hydrogen bonds originating from the 14 water O—H groups, O_{2w}—H₀₃ being involved in a three-centre bond. One branch of the latter connects [Ca(H₂O)₇]²⁺ cations. The other O—H · · A interactions exhaustively use the N and O atoms of the anions as acceptors; O₁, O₂, O₇ and O₈ act as bifunctional acceptors in bifurcated hydrogen bonds, with the N atoms and the remaining O atoms acting as monofunctional acceptors.

Experimental

Crystals of (1) were obtained in 85% yield by adding 0.17 g (2.3 mmol) Ca(OH)₂ dissolved in 20 ml deionized water to 1.00 g (4.56 mmol) 1,2-benzenedisulfonimide (Hendrickson, Okano & Bloom, 1969; Blaschette *et al.*, 1993) in 100 ml deionized water, stirring the resulting solution for 3 h, evaporating the heated solution to 3 ml and storing at ambient temperature. The crystals deliquesce at 333 K. Elemental analysis: found C 23.94, H 3.67, N 4.68, S 21.23%; C₁₂H₂₂CaN₂O₁₅S₄ requires C 23.92, H 3.68, N 4.65, S 21.28%.

(Received 27 September 1996; accepted 10 February 1997)

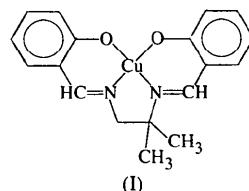

Abstract

In the title compound, [Cu(C₁₈H₁₈N₂O₂)], the coordination geometry about the Cu atom is a 6–5–6 chelate ring structure, with a tetrahedrally distorted square plane composed of two imine N atoms and two phenol O atoms. The angle between the two planes, which each contain the donor atoms of a salicylidiminato residue, and the central Cu atom is 15.8(2)°.

† Alternative name: {2,2'-(2-methyl-1,2-propanediylbis(nitrilomethylene))diphenolato-N,N',O,O'}copper(II).

Comment

Copper(II) complexes with tetradeinate imine–phenols have been extensively investigated for their colour isomerism (Llewellyn & Waters, 1960; Hall & Waters, 1960), conformational influences (Clark, Hall & Waters, 1969; Baker, Hall & Waters, 1970a,b) and potential as radiopharmaceuticals (John, Bott & Green, 1994). We describe here the synthesis and characterization of the title complex, (I).

The Cu atom is four-coordinated by an N₂O₂ donor set from the imine–phenol ligand in a tetrahedrally distorted square-planar coordination geometry with the two phenolate O atoms being deprotonated. The donor atoms do not form a perfect plane but deviate by 0.190(4) Å from their best plane. The ethylenediamine C15 and C16 atoms are displaced by 0.308(4) and 0.289(4) Å, respectively, in opposite directions from the CuN₂ plane. The Cu–N and Cu–O bond lengths are similar to those found in analogous structures (1.904–2.000 Å for Cu–N and 1.886–1.945 Å for Cu–O; Baker, Hall & Waters, 1970a; Cheeseman, Hall & Waters, 1966; Bhadbhade & Srinivas, 1993).

Perhaps the most interesting comparative aspect of copper(II) complexes with tetradeinate imine–phenols involves the steric influence of (i) the length of the alkylene backbone, (ii) substitution in the alkylene bridge, and (iii) substitution in the aromatic rings upon the molecular structure. The title compound displays monomeric and four-coordinate geometry which is consistent with that of copper(II)–imine–phenols with a four-coordinate structure (Baker, Hall & Waters, 1970a; Bhadbhade & Srinivas, 1993; Cheeseman, Hall & Waters, 1966; Lu, Yao, Lo & Tung, 1997; Yao, Lo, Chen & Lu, 1997). This configuration is significantly distinct from monomeric Cu^{II}–N,N'-bis(salicylidene)-1,2-diiminopropane–H₂O (Llewellyn & Waters, 1960) and other dimeric copper(II)–imine–phenols with five-coordinate structures (see Table 2).

The distortion of the inner coordination sphere can be recognized by the dihedral angles between the planes defined by Cu1, N1, O1 and Cu1, N2, O2. It is seen that the dihedral angle for (I), 15.8(2)°, is much larger than that of monomeric Cu^{II}–N,N'-bis(salicylidene)diiminoethane [5.3(2)°; Baker, Hall & Waters, 1970a] and that of Cu^{II}–N,N'-bis(5-chlorosalicylidene)-1,2-diiminoethane [9.2(3)°; Bhadbhade & Srinivas, 1993] with substitution of Cl atoms in the aromatic rings. The effect of dimethyl substitution in the ethylene
