One butyl group, C39—C41, is disordered over two positions. The maximum difference peak of 1.5 e Å<sup>-3</sup> lies near C114 (in the  $PCl_6^-$  anion) and may indicate a minor disorder component (or atomic displacements not well approximated by ellipsoids).

## Abstract

The single-crystal X-ray structure determination of enantiomerically pure (*4R,5S*)-3-[*(2R,3S*)-3-hydroxy-2-methyl-7-octynoyl]-4-methyl-5-phenyl-1,3-oxazolidin-2-one,  $C_{19}H_{23}NO_4$ , at 223 K is reported. The absolute configuration of this molecule has been determined.

## Comment

(*4R,5S*)-3-[*(2R,3S*)-3-Hydroxy-2-methyl-7-octynoyl]-4-methyl-5-phenyl-1,3-oxazolidin-2-one, (1), was prepared as an important intermediate in the asymmetric synthesis of the  $\beta$ -amino acid and  $\beta$ -hydroxy acid derivatives of oncidins (Rodríguez *et al.*, 1994; Fernández *et al.*, 1996), dimeric depsipeptides from the mollusc *Oncidium sp.* Compound (1) has been synthesized from enantiomerically pure commercially available (*1S,2R*)-norephedrine (Fernández *et al.*, 1996), thus fixing the absolute configurations of C atoms 4 and 5 in the title compound. This allows determination of the absolute configuration at C atoms 2' and 3', which is important in the context of the synthetic strategy to control the stereochemistry of the final  $\beta$ -hydroxy and  $\beta$ -amino acids.

A view of (1) showing the displacement ellipsoids, atomic numbering and the correct absolute configuration is given in Fig. 1. The absolute configuration of the molecule was also determined by refinement of the structure according to the method of Flack (1983).

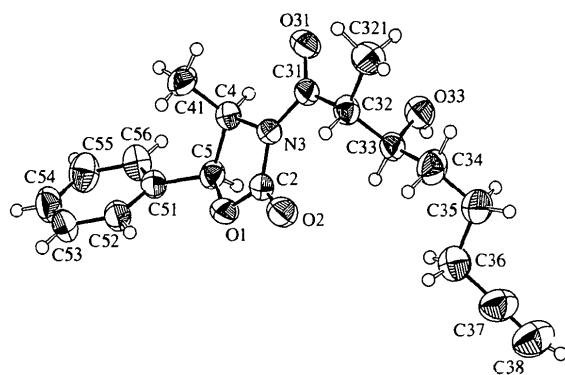

Fig. 1. Diagram of the molecule showing the atom-labelling scheme. Displacement ellipsoids are drawn at the 60% probability level. H atoms are represented by spheres of arbitrary size.

The X-ray analysis supports the expected (Evans, Bartroli & Shih, 1981; Gage & Evans, 1989) configuration at all the chiral centres. The torsion angles C321—C32—C33—O33 and C41—C4—C5—C51 are  $-61.8(2)$  and  $26.9(3)^\circ$ , respectively. Bond lengths and angles in this compound fall within normal ranges. The oxazolidinone ring has structural features that are comparable with those of similar compounds (Marsch, Schaefer, Kukkola & Myers, 1992), being non-planar; the atom set N3, C2, O2, O1 defines a virtual plane, but atom C4 sits above and atom C5 sits below this plane.

## Experimental

Compound (1) was prepared in optically pure form by an enantioselective aldol condensation reaction using Evans' methodology (Evans *et al.*, 1981; Gage & Evans, 1989). Suitable crystals were obtained from an ethyl acetate–hexane (1:6) solution.

(Received 6 January 1997; accepted 5 March 1997)

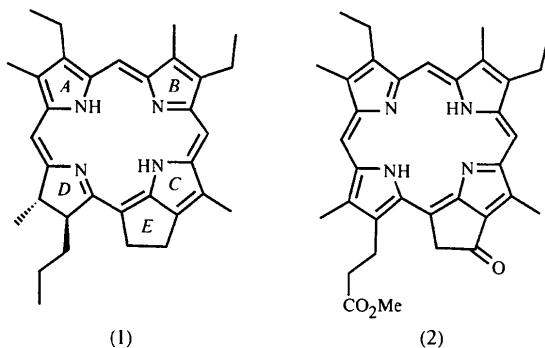

### Abstract

The crystal and molecular structures of 17-decarboxyethyl-13<sup>1</sup>-deoxo-17-propylphytochlorin,  $C_{33}H_{40}N_4$ , (1), and phytoporphyrin methyl ester,  $C_{34}H_{36}N_4O_3$ , (2), are compared. Compound (1) shows structural parameters similar to those of other naturally occurring phytochlorins. Owing to the absence of any heteroatom functionalities at the periphery, no close contacts are observed in the packing of (1), in contrast to those normally found in other chlorophyll derivatives. Compound (2) presents the first structure of a free-base pheophorphyrin and forms chains stabilized by  $C-H \cdots O=C$  and  $\pi-\pi$  interactions.

In contrast to the structure of (1) and other chlorins, the two pyrrole H atoms in (2) are located at rings *B* and *D*.

### Comment

The structure of the phytochlorin (1) derived from chlorophyll *a* was determined in order to obtain information on the crystal packing of a pheophorbide *a* derivative containing no O functionalities. This was achieved in (1) by removal of the 13<sup>1</sup> oxo group and substitution of the 17-propionic acid group present in chlorophyll *a* with a propionyl group.

Compound (1) crystallized with two crystallographically independent molecules in the asymmetric unit, mainly distinguished by the conformation of the C17 propionyl groups (Fig. 1). The structural parameters of the macrocycles agree well with those of other pheophorbides related to chlorophyll *a* (Hoppe, Will, Gassmann & Weichselgartner, 1969; Gassmann, Strell, Brandl, Sturm & Hoppe, 1971; Fischer, Templeton, Zalkin & Calvin, 1972; Kratky, Isenring & Dunitz, 1977; Smith, Goff, Fajer & Barkigia, 1982, 1983; Senge & Smith, 1992). The hydroporphyrin character is clearly evidenced by the elongated C17–C18 and C37–C38 bond lengths [1.552(5) and 1.551(5) Å, respectively]. With the exception of the reduced ring *D*, both macrocycles are almost planar. The average deviation of the 26 atoms comprising the phytochlorin macrocycle system is 0.031 Å in (1) and 0.065 Å in (2). The largest deviations from the respective N<sub>4</sub> planes are observed for C18 [0.28(5) Å] and C38 [0.42(5) Å].

The chlorins form molecular stacks in the crystal, repeating the (1)–(1)–(2)–(2)–(1) motif. Whereas the interplanar separations of the N<sub>4</sub> planes are of the order of 3.5 Å, there is almost no  $\pi$  overlap of the ring systems as indicated by center-to-center separations of the order of 7.9(1) Å and lateral shifts of the macrocycle centers against each other by about 7.03(3) Å [geometrical parameters as defined by Scheidt & Lee (1987)]. Thus, in contrast to other phytochlorins, in the absence of any heteroatom functionalities at the phytochlorin periphery, no close contacts and only very weak  $\pi-\pi$  interactions are observed.
