geometry. What influences lead to this relatively uncommon geometry remain to be understood. The compound (Et_3NH) [Cd{S(O)CPh}] was synthesized during an attempt to prepare $Ba[Cd{S(O)CPh}_3]_2$. The structure of the new salt, (I), allows an investigation of the influence of the counterion and hydrogen bonding on the configuration of the $[Cd{S(O)CPh}_3]^-$ anion. The synthesis and structural findings are reported in this paper.

Abstract

The synthesis and structure of the title compound, $(C_6H_{16}N)[Cd(C_7H_5OS)_3]$, are reported. There are two independent formula units in the asymmetric unit. In each $[Cd{S(O)CPh}_3]^-$ anion, the Cd^{II} atom is located in the plane of the three S atoms. The Cd-S distances are 2.489(1), 2.496(1) and 2.547(1) Å in ion-pair (1), and 2.505(1), 2.515(1) and 2.592(1) Å in ionpair (2). In addition, there are weak intramolecular interactions between the Cd and carbonyl O atoms $[Cd \cdots O 2.537(2), 2.663(2) \text{ and } 3.111(2) \text{ Å in } (1), \text{ and }$ 2.464 (2), 2.677 (2) and 2.718 (2) Å in (2)]. Each cationanion pair is linked by a strong N-H...O hydrogen bond, with respective O···H and O···N distances of 1.925 (3) and 2.834 (3) Å in (1), and 1.886 (2) and 2.789(2) Å in (2).

Comment

We have been interested in the chemistry and structures of thiobenzoate complexes and have described previously the structures of $(R_4E)[M{S(O)CPh}_3]$ [R = Ph, E = As or P, M = Zn, Cd, Hg (Vittal & Dean, 1996a) orPb (Burnett et al., 1994); R = Me, E = N, M = Sn (Vittal & Dean, 1996b) or Hg (Vittal & Dean, 1997)], as well as $(Me_4N)[Na{Cd}[S(O)CPh]_3]_2]$ (Vittal & Dean, 1993). In the case of the complexes containing the zinc-group metals, the MS_3 cores were found to adopt a planar 319

The single-crystal X-ray diffraction analysis of (I) shows that there are two independent formula units in the asymmetric unit. No crystallographically imposed symmetry is present. There are close hydrogen-bonding interactions between the anions and cations. However, an extended hydrogen-bonded network appears to be absent. Views of the ion pairs (1) and (2) are shown in Figs. 1(a) and (1b), respectively. Selected bond distances and angles are given in Table 1, and the hydrogenbonding parameters are shown in Table 2. In each ion pair, the three S(O)CPh⁻ ligands are bonded to the Cd^{II} atom primarily through their S atoms. Neglecting the weak interactions with the O atoms, the coordination kernels approximate planar CdS₃. The sum of the S---Cd---S angles are 358.53(5) and $355.80(5)^{\circ}$ for (1) and (2), respectively. For comparison, this sum is 359.99 (10)° in [Ph₄As][Cd{S(O)CPh}₃] (Vittal & Dean, 1996a). The deviations of the Cd atoms from the S₃ planes are 0.176 (1) and 0.298 (1) Å, respectively, for ion-pairs (1) and (2). In a similar manner, the metal atoms are 0.403(1) and 0.226(1) Å away from the O_3 planes in (1) and (2), respectively. The phenyl rings are twisted from the C, O, S planes; the angles vary from 13.4 (3) to 21.4 (2)° in (1) and from 14.0 (3) to $32.6(1)^{\circ}$ in (2).

The Cd—S distances in Table 1 are comparable to the values of 2.453 (2), 2.514 (2) and 2.545 (2) Å found for the Ph₄As⁺ salt (Vittal & Dean, 1996a). It is obvious that two of the S---Cd---S angles are similar but significantly different from the third. All the Cd. . . O distances, with the exception of Cd1-O3, are within the limits of the sum of the van der Waals radii (3.1 Å; Bondi, 1964). If we take into account these weak Cd-O interactions, then the coordination geometry of the Cd^{II} atom is best described as a distorted trigonal bipyramid for (1) and a distorted octahedron for (2). The total bond valence (Brown & Altermatt, 1985) of cadmium in the ion pairs is 2.01 in both (1) and (2), with the interaction with oxygen providing 17 and 23% of the total. For comparison, values of 2.18 and 20% were found for the corresponding Ph₄As⁺ salt (Vittal & Dean, 1996*a*). It is noted that the PhC(O)S⁻ anion that has the shortest Cd—O distance has the longest Cd—S distance. The O atom that has the longest Cd···O distance in (1) and (2) participates in hydrogen bonding to an Et₃NH⁺ ion as indicated by the N···O distances [2.834 (3) Å for (1) and 2.789 (2) Å for (2)]. As shown in Table 2, the N—H···O

(b)

angles are close to linearity. The presence of strong hydrogen bonding did not affect the planarity of the CdS₃ skeleton, but instead led to different orientations of the carbonyl groups around the Cd atom. Two such conformations were 'trapped' in the present study. It appears that the intriguing CdS₃ planar conformation in the [Cd{S(O)CPh}₃]⁻ ion is independent of the nature of the counterion or hydrogen bonding as established in this work.

The packing of the two ion pairs in the crystal lattice is shown in Fig. 2. When viewed down the c axis, the structure appears to be pseudo-trigonal.

Experimental

All the chemicals were of reagent grade and were used as received. The synthesis was carried out under an argon atmosphere. The product, (C₆H₁₆N)[Cd(C₇H₅OS)₃], was obtained in an attempted synthesis of $Ba[Cd(C_7H_5OS)_3]_2$. Thiobenzoic acid (2.35 g, 17.0 mmol) in 15 ml of methanol was added to Et₃N (1.55 g, 17.0 mmol). The resultant yellow solution of Et₃NH⁺.S(O)CPh⁻ was added with stirring to a solution of [Cd(NO₃)₂].4H₂O (1.57 g, 5.1 mmol) dissolved in 10 ml of water to give a milky supernatant and a yellow precipitate. Addition of a solution containing BaCl₂ (0.53 g, 2.55 mmol) in 10 ml of water produced a colorless upper layer and a yellow lower layer. The mixture was stirred for 10 min and then the two layers were separated. About 20 ml of Et₂O was layered onto the yellow fraction and the mixture was allowed to stand in a refrigerator at 278 K. The yellow crystals that formed were decanted, washed with Et₂O and dried in air. A second crop of crystals was obtained from the mixture of mother liquor and washings. Total yield: 2.6 g (81.4%). Single crystals were

formed during the preparation. The stoichiometry of the bulk material was confirmed by analysis of a ¹H NMR spectrum in CDCl₃.

The diffraction experiments were carried out on a Siemens SMART CCD diffractometer with an Mo $K\alpha$ sealed tube at 296 K. Preliminary cell constants were obtained from 45 frames (width of 0.3° in ω). Final cell parameters were obtained by global refinements of reflections obtained from integration of all the frame data. A frame width of 0.3° in ω and a counting time of 20 s per frame at a crystal-to-detector distance of 4.95 cm were used. The collected frames were integrated using the preliminary cell-orientation matrix. The software SMART (Siemens, 1996a) was used for collecting frames of data, indexing reflections and determination of lattice parameters, SAINT (Siemens, 1996a) for integration of intensity of reflections and scaling, SADABS (Sheldrick, 1996) for absorption correction and SHELXTL (Siemens, 1996b) for data reduction, space-group determination, structure determination and refinements, graphics and structure reporting.
