#### Abstract

Treatment of $\alpha$-naphthyl phenyl ketone with Zn /acetic acid gives racemic $\alpha$-naphthyl phenyl pinacol [1,2-di(1-naphthyl)-1,2-diphenylethane-1,2-diol], $\mathrm{C}_{34} \mathrm{H}_{26} \mathrm{O}_{2}$, but reaction with $\mathrm{Mg} / \mathrm{MgI}_{2}$ gives a product which proves to be not a pinacol, but a tricyclic compound (with four chiral centers, formed by addition at the 2 -position of one of the naphthalene groups), racemic 5-(1-naphthyl)-3,5-diphenyl-4-oxatricyclo[7.4.0.0 ${ }^{2.6}$ ]trideca-7,9,11,13-tetraen-3-ol, $\mathrm{C}_{34} \mathrm{H}_{26} \mathrm{O}_{2}$. The aromatic ring in this tricyclic compound is planar, but the other six-membered ring, and the five-membered furano ring, are non-planar. Bond lengths and angles in both molecules correspond to the molecular formulations. In both structures, the OH groups are involved in only weak intermolecular interactions.

## Comment

Glycols, which may be synthesized by the dissolvingmetal reduction of ketones, undergo dehydration and skeletal rearrangement when treated with mineral acids, a process known as the pinacol rearrangement. A study of the rearrangement of benzpinacols was initiated, in order to obtain details of the geometrical parameters in solid-state reactions (cf. Jones et al., 1989; Toda \& Shigemasa, 1989; Chen et al., 1991). For various reasons this study was discontinued, but some interesting results did emerge, which shed light on some longoutstanding ambiguities.

Reduction of $\alpha$-naphthyl phenyl ketone (1-benzoylnaphthalene), (1), with Zn /acetic acid is reported to produce a material with m.p. 431 K , while reduction with $\mathrm{Mg} / \mathrm{MgI}_{2}$ gives a different material, with m.p. 493 K (Bachmann \& Shankland, 1929; Bergmann \& Schuchardt, 1931). Although not specifically stated, the implication is that these materials are racemic, (2), and meso forms, respectively, of di- $\alpha$-naphthyl diphenyl pinacol. These syntheses have been repeated, giving crystalline materials with m.p. 421 and 479 K (see supplementary material). X-ray analysis of the lower-melting
crystals indicates that the compound is racemic (2). The higher-melting material proves to be racemic (3), a tricyclic compound (with four chiral centers), formed as a result of addition at the 2-position of one of the naphthalene groups.

(1)

(2)
$\mathrm{Mg}^{\mathrm{MgI}} 2$

(3)

Room-temperature Rigaku AFC-6 data for (2) yielded a structure which did not refine satisfactorily. The structure of (3) was determined initially with roomtemperature Rigaku AFC-6 diffractometer data (University of British Columbia, UBC), and later with Rigaku R-axis II image-plate data (Chinese University of Hong Kong, CUHK). Cell parameters showed differences of $8-18 \sigma$, suggesting typical underestimation of errors (Taylor \& Kennard, 1986). Differences between the two sets of positional and displacement parameters were examined by half-normal probability plots (Abrahams \& Keve, 1971), which gave reasonably straight lines through the origin, slopes of 1.3-1.5, again suggesting some underestimation of errors. The main difference was that $U_{22}$ (CUHK) were nearly all greater than $U_{22}(\mathrm{UBC})$, by a mean of $1.9 \sigma$ and maximum of $4.5 \sigma$; this suggested possible errors in (or a need for) absorption corrections for the needle-shaped crystals. To establish both crystal structures definitively, new data had been measured at 180 K with a Rigaku/ADSC CCD area detector (UBC).
Compound (2) is racemic $\alpha$-naphthyl phenyl pinacol, the molecule having approximate (non-crystallographic) $C_{2}$ symmetry (Fig. 1 shows the $R, R$ enantiomer). The molecular dimensions are close to normal, except for a long central $\mathrm{C} 1-\mathrm{C} 2$ bond of 1.618 (2) $\AA$. In the tricyclic ring system of (3) (Fig. 2), the aromatic ring is planar, but the other two rings show deviations from planarity (roughly $\mathrm{C}_{3}$ envelopes). Bond lengths and angles correspond to the molecular formulation (3), with $\mathrm{ClO}=\mathrm{Cll}$ definitely a double bond [1.336(3) A]. Neither structure exhibits strong hydrogen bonds: (2)
has a weak $\mathrm{O} 1-\mathrm{H} \cdot \mathrm{O} 2$ intermolecular interaction $\left[\mathrm{O} \cdots \mathrm{O}=2.937(2) \AA\right.$ and $\left.\mathrm{O}-\mathrm{H} \cdots \mathrm{O}=116(2)^{\circ}\right]$, and possible $\mathrm{O} 2-\mathrm{H} \cdots \pi$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ interactions; (3) exhibits possible $\mathrm{O}-\mathrm{H} \cdots \pi$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ interactions (cf. e.g. Ferguson et al., 1995). The $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ interactions are all weak, with $\mathrm{C} \cdots \mathrm{O}=2.7-2.9, \mathrm{H} \cdots \mathrm{O}=$

Fig. 1. View of the molecule of (2). Displacement ellipsoids are shown at $50 \%$ probability.

Fig. 2. View of the molecule of (3). Displacement ellipsoids are shown at $50 \%$ probability.
2.3-2.6 $\AA$, and $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}=90-120^{\circ}$. The $\mathrm{O}-\mathrm{H} \cdots \pi$ interactions also do not appear to be particularly strong, with $\mathrm{H} \cdots \mathrm{C}=\mathrm{C}_{\text {aromatic }}$ distances in the range $2.3-2.5 \AA$ and $\mathrm{O}-\mathrm{H} \cdots \pi$ angles of $120-147^{\circ}$.

Attempts to refine the Flack parameter (Flack, 1983) with TEXSAN (Molecular Structure Corporation, 1992-97) and with SHELXL97 (Sheldrick, 1997) were unsuccessful (not surprising, with light-atom structures and Mo radiation). Hence, the polarity of the crystal of (2) and the absolute configuration of the crystal of (3) are undetermined. The bulk sample of (3) presumably contains equal amounts of both enantiomers.

For both compounds, data collection: $d^{*}$ TREK (Molecular Structure Corporation, 1997); cell refinement: $d^{*}$ TREK; data reduction: TEXSAN (Molecular Structure Corporation, 19921997): program(s) used to solve structures: SIR92 (Altomare et al., 1993); program(s) used to refine structures: TEXSAN; software used to prepare material for publication: TEXSAN.

We thank the Ho Sin-Hang Education Endowment Fund for a Named Professorship (JT), and the Hong Kong Research Grants Council (CUHK 456/95P) and
the Natural Sciences and Engineering Research Council of Canada for financial support.

Supplementary data for this paper are available from the IUCr electronic archives (Reference: FGl438). Services for accessing these data are described at the back of the journal. Synthesis and spectroscopic analysis details have also been deposited

#### Abstract

The title compound, $\mathrm{C}_{14} \mathrm{H}_{12} \mathrm{~N}_{2} \mathrm{O}_{2} \mathrm{~S}$ (ENP), is a precursor in the synthesis of antipsychotic drugs based on 3-nitro-

phenothiazines. The structure analysis confirms the expected 3-nitro derivative. The nitro group flattens the tricycle; the dihedral angle between the phenyl rings is $157.2(1)^{\circ}$, compared with a value of $135.2(1)^{\circ}$ in the non-nitrated compound.

## Comment

Phenothiazines having different substituents have been systematically synthesized in order to find new antipsychotic drugs. The title compound, ENP, is an intermediate in the synthesis of active 3-nitrophenothiazinic compounds.

The structural study of ENP was undertaken in order to confirm the position of the nitro group and the transposition of the phenyl group corresponding to the Smiles rearrangement (Levy et al., 1931).

The folding of the molecule is characterized by the angle between the phenyl planes, whose value is $157.2(1)^{\circ}$. In the non-nitrated compound, 10 -ethylphenothiazine (Chu \& van der Helm, 1975), the corresponding angle is $135.2(1)^{\circ}$, which suggests that addition of groups to the phenyl rings flattens the tricycle. This tendency is also observed in the structure of the dibromo-substituted compound, 3,7-dibromo-10ethylphenothiazine (Meester et al., 1986), in which the folding angles are $156.3(2)$ and $145.3(2)^{\circ}$ in the two independent molecules.

In ENP, the ethyl group is almost orthogonal to the thiazine ring, the torsion angle $\mathrm{C} 9-\mathrm{N} 10-\mathrm{Cl1}-\mathrm{C} 12$ being $-84.9(2)^{\circ}$; the corresponding angle is $146.1(4)^{\circ}$ in the non-nitrated compound (Chu \& van der Helm, 1975). The nitro group is almost coplanar with its

Fig. 1. The molecular structure of ENP shown with $50 \%$ probability displacement ellipsoids.
