(Received 31 October 1997; accepted 3 March 1998)

Abstract

The title compound, triammonium dizinc vanadium bis(phosphate) bis(hydrogen phosphate), $(\text{NH}_4)_3\text{Zn}_2\text{V}(\text{PO}_4)_2(\text{HPO}_4)_2$, is the first ammonium zinc vanadium phosphate. It is built up from a three-dimensional network of vertex-sharing VO_6 octahedra and ZnO_4 , PO_4 and HPO_4 tetrahedra fused together via $\text{V}—\text{O}—\text{P}$ and $\text{Zn}—\text{O}—\text{P}$ bonds [$d_{\text{av}}(\text{V}—\text{O}) = 2.001 (2)$, $d_{\text{av}}(\text{Zn}—\text{O}) = 1.949 (2)$ and $d_{\text{av}}(\text{P}—\text{O}) = 1.538 (2) \text{ \AA}$; $\theta_{\text{av}}(\text{V}—\text{O}—\text{P}) = 142.5$ and $\theta_{\text{av}}(\text{Zn}—\text{O}—\text{P}) = 131.6^\circ$]. NH_4^+ cations occupy two different types of interstices in the $\text{Zn}—\text{V}—\text{P}—\text{O}$ framework.

Comment

Vanadium(III) phosphates have been structurally characterized only recently (Lavrov *et al.*, 1981; Lii *et al.*, 1992; Haushalter *et al.*, 1995). Here, we describe the synthesis and characterization of $(\text{NH}_4)_3\text{Zn}_2\text{V}(\text{PO}_4)_2(\text{HPO}_4)_2$, the first ammonium zinc vanadium(III) phos-

phate. This phase (Fig. 1) is built up from a three-dimensional framework of VO_6 octahedra and ZnO_4 , PO_4 and HPO_4 tetrahedra sharing vertices as $\text{V}—\text{O}$ —P and $\text{Zn}—\text{O}—\text{P}$ bonds. Extra-framework NH_4^+ cations complete the structure.

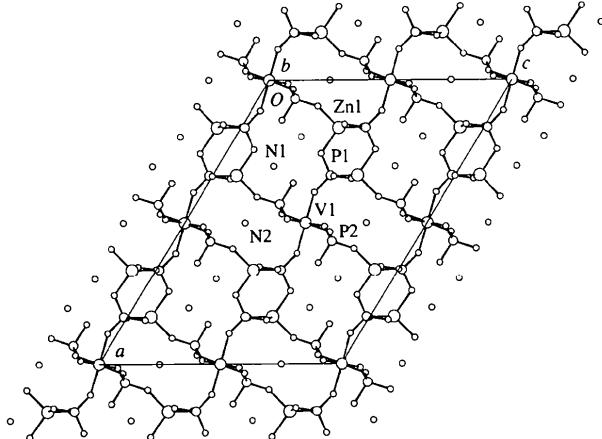

Fig. 1. View of the $(\text{NH}_4)_3\text{Zn}_2\text{V}(\text{PO}_4)_2(\text{HPO}_4)_2$ structure down [010].

The VO_6 octahedron is close to being regular (the V site symmetry is $\bar{1}$), with $d_{\text{av}}(\text{V}—\text{O}) = 2.001(2)$ Å. The bond-valence sum (BVS; Brown, 1996) for this atom is 2.99 [the expected value for vanadium(III) is 3.00]. Other ammonium vanadium(III) phosphates (Haushalter *et al.*, 1995; Bircsak & Harrison, 1998) show a similar, essentially regular, octahedral coordination for the VO_6 grouping, which is quite distinct from the asymmetric coordination favoured by V^{IV} and V^V compounds (Jordan & Calvo, 1973; Amorós & Le Bail, 1992). This VO_6 group forms six links to adjacent P atoms, with an average $\text{V}—\text{O}—\text{P}$ bond angle of 142.5° . The ZnO_4 tetrahedron [$d_{\text{av}}(\text{Zn}—\text{O}) = 1.949(2)$ Å, BVS(Zn) = 2.07] is typical for this species (Feng *et al.*, 1997) and forms four $\text{Zn}—\text{O}—\text{P}$ bonds ($\theta_{\text{av}} = 131.6^\circ$). The two phosphate tetrahedra [$d_{\text{av}}(\text{P}1—\text{O}) = 1.538(2)$ and $d_{\text{av}}(\text{P}2—\text{O}) = 1.539(2)$ Å; BVS(P1) = 4.95 and BVS(P2) = 4.96] are also typical. The longer terminal $\text{P}2—\text{O}8$ bond suggests that this vertex is protonated (Lightfoot & Masson, 1996). This is supported by the fact that the valence of O8 is 1.06 when considering only its connectivity to P2. P1 makes one $\text{P}—\text{O}—\text{V}$ and three $\text{P}—\text{O}—\text{Zn}$ links; P2 makes two $\text{P}—\text{O}—\text{V}$ links and one $\text{P}—\text{O}—\text{Zn}$ link, and has one terminal $\text{P}—\text{OH}$ vertex.

The polyhedral connectivity in $(\text{NH}_4)_3\text{Zn}_2\text{V}(\text{PO}_4)_2(\text{HPO}_4)_2$ may be visualized as the fusing of two types of chains propagating in the [010] direction. The first chain (Fig. 2) consists of a backbone of VO_6 octahedra and $\text{P}2\text{O}_4$ tetrahedra. Polyhedral four-rings (two octahedra plus two tetrahedra) arise from this topology, which has also been observed as a building

unit in $\alpha\text{-NH}_4\text{V}(\text{HPO}_4)_2$ (Bircsak & Harrison, 1998) and $\beta\text{-NH}_4\text{V}(\text{HPO}_4)_2$ (Haushalter *et al.*, 1995). A pair of $\text{P}1\text{O}_4$ groups are also bound to each V atom in a *trans* configuration.

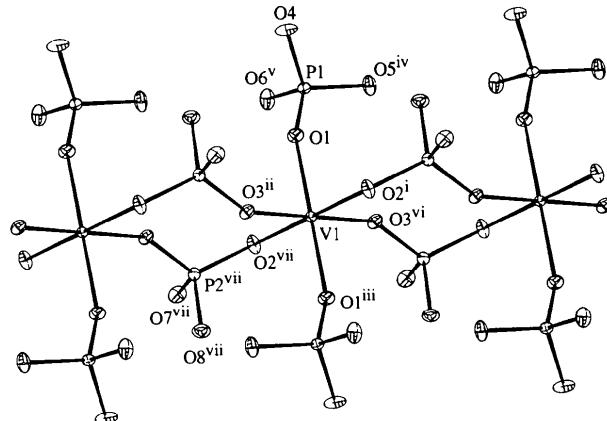

Fig. 2. View of the V-P-O chain in $(\text{NH}_4)_3\text{Zn}_2\text{V}(\text{PO}_4)_2(\text{HPO}_4)_2$. Displacement ellipsoids are shown at 50% probability. Symmetry codes: (i) $\frac{1}{2} - x, -\frac{1}{2} + y, \frac{1}{2} - z$; (ii) $\frac{1}{2} - x, \frac{1}{2} + y, \frac{1}{2} - z$; (iii) $-x, -y, -z$; (iv) $\frac{1}{2} - x, -\frac{1}{2} - y, -z$; (v) $\frac{1}{2} - x, \frac{1}{2} - y, -z$; (vi) $-\frac{1}{2} + x, -\frac{1}{2} - y, -\frac{1}{2} + z$; (vii) $-\frac{1}{2} + x, \frac{1}{2} - y, -\frac{1}{2} + z$.

The second chain subunit (Fig. 3) consists of a ladder-like arrangement of edge-sharing four-rings of alternating ZnO_4 and $\text{P}1\text{O}_4$ tetrahedra. A hanging $\text{P}2\text{O}_4$ group, attached to the Zn centre, completes this chain configuration. This zincophosphate four-ring ladder has a structural precedent in phases such as $\text{CsZn}_3(\text{HPO}_4)_2(\text{PO}_4)$ (Feng *et al.*, 1997) and $\text{H}_3\text{N}(\text{CH}_2)_3\text{NH}_3\cdot\text{Zn}(\text{HPO}_4)_2$ (Harrison *et al.*, 1998). The ladder-like chains in these phases also contain a hanging phosphate group

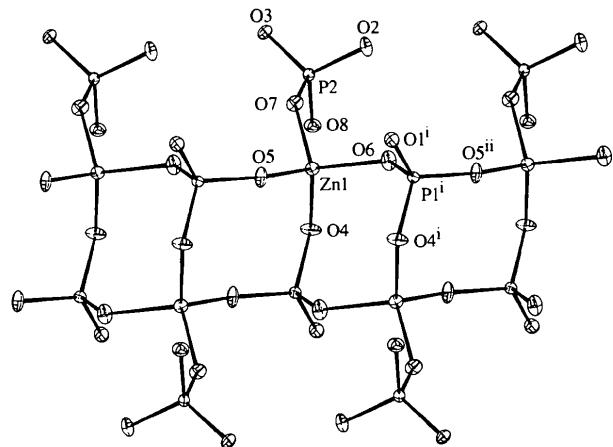

Fig. 3. View of the Zn-P-O chain in $(\text{NH}_4)_3\text{Zn}_2\text{V}(\text{PO}_4)_2(\text{HPO}_4)_2$. Displacement ellipsoids are shown at 50% probability. Symmetry codes: (i) $\frac{1}{2} - x, \frac{1}{2} - y, -z$; (ii) $x, 1 + y, z$.

attached to Zn. The unusual one-dimensional phase $\text{CN}_3\text{H}_6\cdot\text{ZnCl}(\text{HPO}_4)$ (Ng & Harrison, 1998) also contains a four-ring ladder of Zn- and P-centred tetrahedra, with a terminal chloride ion replacing the hanging PO_4 moiety. Similar four-ring ladders are recognized as building units in three-dimensional aluminosilicate zeolite frameworks (Smith, 1988; Feng *et al.*, 1997).

The two distinct ammonium cations occupy voids, visible as small channels propagating in the [010] direction. No details of the hydrogen-bonding situations, if any, of these species could be determined in the present diffraction experiment. If a maximum N···O contact distance of 3.4 Å is assumed, N1 is coordinated by 11 framework O atoms [$d_{av} = 3.105(3)$ Å] and N2 is coordinated by eight framework O atoms [$d_{av} = 2.913(3)$ Å].

Experimental

Single crystals of $(\text{NH}_4)_3\text{Zn}_2\text{V}(\text{PO}_4)_2(\text{HPO}_4)_2$ were synthesized from a mixture of guanidinium carbonate [$(\text{CN}_3\text{H}_6)_2\text{CO}_3$, 0.95 g], ZnO (0.43 g), 85% H_3PO_4 (2.40 g), VCl_3 (0.82 g) and deionized water (7 ml) (starting molar ratio of N:Zn:V:P = 12:1:1:4). The mixture was sealed in a 23 ml Teflon-lined hydrothermal bomb and heated to 453 K for 48 h. After slow cooling, the bomb was opened to reveal a mixture of perfectly faceted yellow-green plates of the title compound (visual yield ~5%), transparent crystals of hopeite [$\text{Zn}_3(\text{PO}_4)_2\cdot 4\text{H}_2\text{O}$] (Whitaker, 1973) and other, unidentified, phases. Syntheses starting from a stoichiometric mixture of precursors, or from a source of ammonium cations, were not successful in preparing $(\text{NH}_4)_3\text{Zn}_2\text{V}(\text{PO}_4)_2(\text{HPO}_4)_2$ in measurable yield.

Abstract

The three-dimensional framework of tetrasodium titanium nonaoxodiarsonate, $\text{Na}_4\text{TiAs}_2\text{O}_9$, consists of infinite $[\text{TiO}(\text{AsO}_4)_2]_n$ chains linked together by Na^+ cations. The structure is compared with those of $\text{Na}_3\text{SbO}(\text{PO}_4)_2$ ($P2_12_12_1$) and $\text{Na}_4\text{TiP}_2\text{O}_9$ ($P2/c$, *Ibam* and *Bmcm*).

Commentaire

Les études effectuées dans les systèmes ternaires $A_2\text{O}-\text{TiO}_2-\text{As}_2\text{O}_5$ ont permis d'isoler la série de formulation $A\text{Ti}_2(\text{AsO}_4)_3$ ($A = \text{Li}, \text{Na}, \text{K}$ et Ag) (Yaakoubi *et al.*, 1991) de type Nasicon caractérisé par une conductivité ionique élevée (Hagman & Kierkegaard, 1968) et les composés $A\text{TiOAsO}_4$ ($A = \text{alcalin}$). Ces derniers adoptent trois types de structures: LiTiOAsO_4 (Robertson *et al.*, 1994) à une charpente tridimensionnelle analogue à celle de $\beta\text{-LiVOPO}_4$ (Lii *et al.*, 1991), le titanyl-arséniate de sodium et de potassium $\text{Na}_{0.87}\text{K}_{0.13}\text{TiOAsO}_4$ (Phillips *et al.*, 1992) isotype de CaTiOSiO_4 (Donnay & Ondik, 1973) et de NaVOAsO_4 (Haddad *et al.*, 1992), et enfin les composés KTiOAsO_4 (El Brahimi & Durand, 1986), CsTiOAsO_4 (Protas *et al.*, 1989), RbTiOAsO_4 (Thomas *et al.*, 1992) et $\text{Ag}_{0.98}\text{K}_{0.02}\text{TiOAsO}_4$ (Phillips *et al.*, 1992) isostructuraux de KTiOPO_4 (Tordjman *et al.*, 1974) connu pour ses propriétés optiques de doubleur de fréquence (Zumesteg *et al.*, 1976). Le présent travail est consacré à la préparation et à l'étude structurale de $\text{Na}_4\text{TiO}(\text{AsO}_4)_2$.

La structure renferme des chaînes d'octaèdres TiO_6 , parallèles à [010], partageant des sommets. Deux octaèdres successifs sont bridgés par deux tétraèdres

AsO_4 (Fig. 1). Chaque chaîne $[\text{TiO}(\text{AsO}_4)_2]_n$ est liée à quatre voisines situées à des distances $\text{Ti}-\text{Ti}$ de 7,72 et 7,94 Å, au moyen de liaisons $\text{Na}-\text{O}$ (Fig. 2).

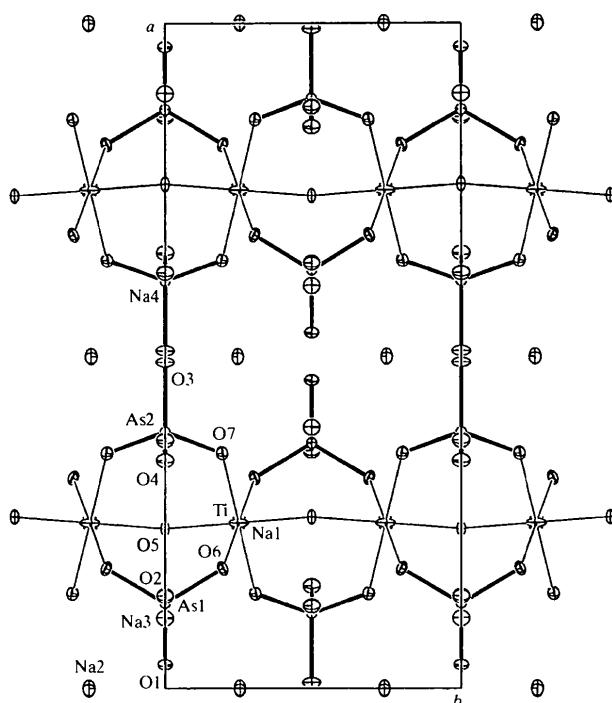

Fig. 1. Projection de la structure de $\text{Na}_4\text{TiAs}_2\text{O}_9$ sur le plan (001). Les ellipsoïdes de vibration des atomes ont une probabilité de 50%.

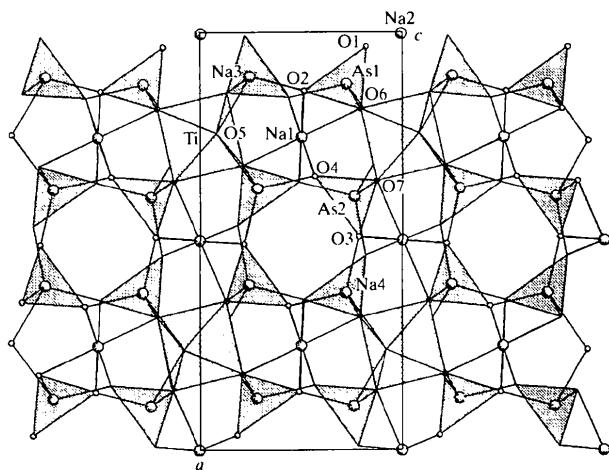

Fig. 2. Projection de la structure de $\text{Na}_4\text{TiAs}_2\text{O}_9$ sur le plan (010).

Les colonnes $[\text{TiO}(\text{AsO}_4)_2]_n$ ménagent entre elles trois types de tunnels partiellement occupés par les ions sodium. Les cations $\text{Na}1$ et $\text{Na}2$ sont situés respectivement dans les sites $4f$ (1) et $4g$ (2) sur les axes des tunnels limités par deux chaînes voisines.
