Interest in the title structure, $\mathrm{C}_{20} \mathrm{H}_{24} \mathrm{O}_{2}$, lies in the novel cis ring junction between the three- and seven-membered rings. This stereochemical arrangement causes the methylene moiety and the cycloheptane ring to be twisted out of the plane of the aromatic ring. The cyclopropane ring is also twisted out of the plane of the aromatic system. The molecules are linked by an $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bond $[\mathrm{O} \cdots \mathrm{O}$ 2.741 (3) Å].

## Comment

Jatropholone (JOH), a natural phorbol-related mixture of diterpenes (JOH-A and JOH-B), was isolated from the hexane extract of Jatropha elliptica (Goulart et al., 1993). Its acetate was characterized previously by X-ray diffraction (Purushothaman et al., 1979). The tetracyclic array, consisting of fused five-, six-, seven- and three-membered rings with two potentially electroactive functionalities, suggests the possibility of interesting chemical transformations. However, apart from the total synthesis (Smith et al., 1986), little chemical information concerning the reactivity has been available. Recently, the diastereomeric mixture was investigated by electroanalysis (De Azevedo et al., 1999) and subjected to electrochemical and chemical reductions. Electrolysis (Hg cathode, dimethylformamide/tetrabutylammonium perchlorate) and catalytic hydrogenation $\left(\mathrm{H}_{2} / \mathrm{PtO}_{2}\right)$ lead, in both processes, to high chemo- and stereoselectivities (De Azevedo et al., 1999). The phenolic proton and the positioning of the seven- and three-membered rings appear to play a very important role in the process. To understand the selectivities, structural information on the non-derivatized substrate is a fundamental requirement. Jatropholone A (JOH-A), (I), was therefore purified and its three-dimensional structure determined by crystallographic analysis.

The five-membered ring has an envelope conformation in which C 5 is 0.259 (5) $\AA$ out of the plane formed by the
remaining four atoms. The Cremer \& Pople (1975) ring puckering parameters are $q_{2}=0.167$ (3) $\AA$ and $\varphi_{2}=85.0(10)^{\circ}$.

(I)

The dihedral angle between the five-membered ring and sixmembered aromatic ring is $5.6(1)^{\circ}$. Atoms C1A and C7 are nearly coplanar with the aromatic ring, with distances of 0.068 (5) and 0.158 (5) $\AA$, respectively, out of that plane. Atom C14 of the methylene group is located above the average plane of the aromatic ring, whereas atom C 1 of the cyclopropane ring is below the plane. The distances of atoms C14 and C1 from this plane are 1.308 (6) and -1.016 (6) $\AA$, respectively.

The absolute stereochemistry could not be determined from the present data. The coordinates reflect only relative stereochemistry at the chiral centres. The stereochemistry of the H atoms of $\mathrm{C} 1 A$ and $\mathrm{C} 9 A$, where the cyclopropane ring is fused to the cycloheptane ring, is cis. As measured by the $\mathrm{C} 6 A-\mathrm{C} 6 B-\mathrm{C} 7-\mathrm{C} 14$ torsion angle, the methylene moiety of the cycloheptane ring is twisted out of the plane of the aromatic ring system by 73.1 (1) ${ }^{\circ}$. The cyclopropane ring is twisted out of the plane of the aromatic system by 48.8 (2) ${ }^{\circ}$. The structure therefore demonstrates that, in the formation of the hydrogenated product JOHH-2, the reaction has occurred on the least sterically hindered side of the molecule.

The molecules are linked by hydrogen bonding; $\mathrm{O} 2 \cdots \mathrm{O} 1^{\mathrm{i}}$ 2.741 (3), $\mathrm{HO} 2 \cdots \mathrm{O}^{\mathrm{i}} 1.96, \mathrm{O} 2-\mathrm{HO} 20.82 \AA$ and $\mathrm{O} 2-$ HO2 $\cdots \mathrm{O} 1^{\mathrm{i}} 159^{\circ}$ [symmetry code: (i) $-\frac{1}{2}+x, \frac{3}{2}-y, \frac{1}{4}-z$ ]. In addition, the shortest $\mathrm{C} \cdots \mathrm{O}$ contact may also represent a

Figure 1
Projection of the title compound, showing the relative stereochemistry, atom labelling and $50 \%$ probability displacement ellipsoids for non-H atoms. H atoms are of arbitrary size.
hydrogen bond; $\mathrm{C} 13 \cdots \mathrm{O} 2^{\mathrm{ii}} 3.335$ (4), $\mathrm{H} 13 A \cdots \mathrm{O} 2^{\mathrm{ii}} 2.52 \AA$ and $\mathrm{C} 13 A-\mathrm{H} 13 A \cdots \mathrm{O} 2^{\mathrm{ii}} 143^{\circ}$ [symmetry code: (ii) $\frac{1}{2}+x, \frac{3}{2}-y$, $\left.\frac{1}{4}-z\right]$.

A ZORTEP (Zsolnai, 1995) illustration of the formula unit is presented in Fig. 1.

## Experimental

After isolation from the hexane extract of the plant named Jatropha elliptica (Goulart et al., 1993), following the Muell (Arg) classification system, the diastereomeric mixture of jatropholones $(0.100 \mathrm{~g})$ was submitted to flash chromatography on a silica-gel (230-400 mesh, Merck) column (internal diameter 2 cm , silica height 31 cm ) using a mixture of hexane/ethyl acetate ( $9: 1 \mathrm{v} / \mathrm{v}$ ) as eluent, collecting fractions of 10 ml . The column chromatography was followed by thinlayer chromatography (TLC) on silica-gel $60 \mathrm{~F}_{254}$ plates (layer thickness 0.2 mm , Riedel-deHaën) using the same eluent and two consecutive runs. TLC spots were visualized by ultraviolet irradiation and were developed using a phosphomolybdic acid solution in ethanol ( $10 \%$ ). The less polar compound (JOH-A) eluted first and was left to crystallize in the same solvent system.

## Crystal data

$$

## Refinement

Refinement on $F^{2}$
$R\left[F^{2}>2 \sigma\left(F^{2}\right)\right]=0.0573$

All the H atoms were located on difference Fourier maps. The H atom positions were fixed and an overall isotropic displacement parameter was refined to $U=0.093$ (4) $\AA^{2}$. The absolute stereochemistry could not be determined from refinement of the present
