Hydrothermally prepared  $\text{La}_2(\text{SeO}_3)_3$  contains a three-dimensional network of  $\text{LaO}_{10}$  polyhedra [ $d_{\text{av}}(\text{La}-\text{O}) = 2.622(3) \text{ \AA}$ ] and  $\text{SeO}_3$  pyramids [ $d_{\text{av}}(\text{Se}-\text{O}) = 1.691(3) \text{ \AA}$ ]. One of the  $\text{SeO}_3$  pyramids is in a general position and the other has crystallographic  $m$  symmetry. There are pseudo-channels in the  $[010]$  direction which are probably associated with the  $\text{Se}^{\text{IV}}$  lone pairs.

## Comment

The lanthanum cation adopts an irregular tenfold coordination, assuming a cut-off of  $2.90 \text{ \AA}$  for the maximum  $\text{La}-\text{O}$  distance [ $d_{\text{av}}(\text{La}-\text{O}) = 2.622(3) \text{ \AA}$ ]. The bond valence sum (BVS) of 3.08, calculated by the Brown (1996) formalism, is close to the expected value of 3.00.

The two distinct selenium(IV) species adopt their characteristic pyramidal coordinations (Wildner, 1991; Harrison, 1999), with  $d_{\text{av}}(\text{Se1}-\text{O}) = 1.690(3) \text{ \AA}$ ,  $\text{BVS}(\text{Se1}) = 4.17$ ,  $d_{\text{av}}(\text{Se2}-\text{O}) = 1.692(3) \text{ \AA}$  and  $\text{BVS}(\text{Se2}) = 4.13$  (expected  $\text{BVS} = 4.00$ ). The Se2 atom has  $m$  symmetry.

The polyhedral connectivity in  $\text{La}_2(\text{SeO}_3)_3$  results in infinite sheets of triangular-face-sharing (*via* O1, O2 and O3) and edge-sharing (*via* O3 and O4)  $\text{LaO}_{10}$  groups arrayed normal to  $[001]$ . The  $\text{Se1O}_3$  group is closely associated with these layers, and the  $\text{Se2O}_3$  group serves to fuse adjacent layers into a

three-dimensional structure. The O5 atom also links adjacent  $\text{LaO}_{10}$  layers *via* an  $\text{La}-\text{O5}(\text{Se2})-\text{La}$  bond. Both  $\text{Se1O}_3$  and  $\text{Se2O}_3$  share an edge with an  $\text{LaO}_{10}$  group (Fig. 1), which is similar to the polyhedral connectivity seen in other rare-earth selenites such as  $\text{Nd}(\text{HSeO}_3)(\text{SeO}_3)\cdot\text{H}_2\text{O}$  (de Pedro *et al.*, 1994). When the structure of  $\text{La}_2(\text{SeO}_3)_3$  is viewed down  $[010]$  (Fig. 2), there appears to be infinite channels of approximate dimension  $3.6 \times 5.5 \text{ \AA}$  (measured atom-to-atom), but these are probably associated with the stereochemically active selenium(IV) lone pairs and do not represent space accessible by other chemical species. Similar pseudo-channels associated with selenium lone pairs have been seen in phases such as  $\text{Bi}_2\text{Cu}(\text{SeO}_3)_4$  (Effenberger, 1996) and  $\text{La}_2\text{Cu}(\text{SeO}_3)_4$  (Harrison & Zhang, 1997).

$\text{La}_2(\text{SeO}_3)_3$  complements  $\text{La}(\text{HSeO}_3)(\text{SeO}_3)$  (Morris *et al.*, 1992) which has a somewhat similar structure involving  $\text{LaO}_{10}$  and  $(\text{H})\text{SeO}_3$  polyhedra sharing edges and faces. However, the latter phase is genuinely layered, with inter-sheet bonding occurring only *via*  $\text{Se}-\text{OH}\cdots\text{O}-\text{Se}$  hydrogen bonds and van der Waals forces.

## Experimental

A starting mixture of ' $\text{H}_2\text{SeO}_3$ ' (dissolved  $\text{SeO}_2$ ) (8 ml, 0.5 M), LiOH (4 ml, 1 M),  $\text{H}_2\text{O}$  (4 ml) and  $\text{La}(\text{NO}_3)_3\cdot 9\text{H}_2\text{O}$  (1.732 g) (Li:La:Se ratio of 1:1:1) was heated to 423 K in a 23 ml-capacity sealed teflon-lined

bomb for 6 d. Upon cooling the bomb to ambient temperature over 2–3 h, the resulting solids [unidentified yellowish powder and transparent plates of  $\text{La}_2(\text{SeO}_3)_3$ ] were recovered by vacuum filtration and washing with water.

## Crystal data
