A single crystal of $\mathrm{MoVAlO}_{7}$, vanadium aluminium molybdate, has been grown. The present structure determination is more precise than a previous powder-pattern investigation [Knorr, Jacubus, Dabrowska \& Kurzawa (1998). Eur. J. Solid State Inorg. Chem. 35, 519-530]. A three-dimensional $\left[\mathrm{MoAlO}_{6}\right]_{n}^{3 n-}$ network surrounds infinite strings of $[\mathrm{VO}]^{3+}$ groups $[\mathrm{V}-\mathrm{O}=1.586$ (4) $\AA$ ] lying in the mirror planes.

## Comment

A detailed study of the $\mathrm{Mo}_{1+x} \mathrm{~V}_{2-x} \mathrm{O}_{8}$ and $\mathrm{V}_{2-x} \mathrm{Mo}_{x} \mathrm{O}_{5}$ phases of the $\mathrm{MoO}_{3}-\mathrm{V}_{2} \mathrm{O}_{5}-\mathrm{V}_{2} \mathrm{O}_{4}$ system has been undertaken in order to determine their homogeneity range domains, the existence of super- or modulated structures and also their magnetic and electric behaviours (Galy et al., 2002). For the former phase, i.e. $\mathrm{Mo}_{1+x} \mathrm{~V}_{2-x} \mathrm{O}_{8}$, synthesized at 903 K , the $x$ limit values have been established as $0.12<x<0.18$; in the meantime, magnetic properties have indicated the presence of $\mathrm{V}^{4+}$ cations, leading to the formulation $\mathrm{Mo}_{1+x}^{6+} \mathrm{V}_{2-2 x}^{5+} \mathrm{V}_{x}^{4+} \mathrm{O}_{8}$, this latter phase being a semiconductor $\left(E_{a}=0.22 \mathrm{eV}\right)$. During an attempt to test the electrical response, a pellet was placed in an alumina crucible and heated to 973 K ; surprisingly, an extremely strong reaction occurred between the $\mathrm{Mo}_{1+x} \mathrm{~V}_{2-x} \mathrm{O}_{8}$ pellet and the crucible. In the complex mixture obtained, one small crystal, nicely prismatic and with a green colour, was detected. This crystal was quite different from the crystals of the phases of our system and was studied by X-ray singlecrystal techniques in order to determine its structure and therefore its chemical composition (see details of the structure determination below).

The crystal structure shows three different types of coordination for the Mo, V and Al atoms. A perspective view, oriented along [010], is shown in Fig. 1. The Mo atom is surrounded by four O atoms, making a regular $\mathrm{MoO}_{4}$ tetrahedron (see Table 1); the V atoms are located inside an oxygenated $\mathrm{VO}_{5}$ square pyramid, while the Al atom is at the centre of a regular octahedron. The $\mathrm{VO}_{5}$ square pyramids share opposite basal edges, alternately pointing up and down, making an infinite string elongated along the helicoidal
twofold axis parallel to [010]. These strings are surrounded by a kind of ring alternately built up of four $\mathrm{MoO}_{4}$ tetrahedra and four $\mathrm{AlO}_{6}$ octahedra through shared corners, ... $\mathrm{Al}-\mathrm{O} 2-$ $\mathrm{Mo}-\mathrm{O} 3-\mathrm{Al} \ldots$ (Fig. 2). Along [010], the two other O atoms of the $\mathrm{MoO}_{4}$ tetrahedron (atom O1 repeated by the mirror plane perpendicular to the $y$ axis) connect two successive $\mathrm{AlO}_{6}$ octahedra which share edges with the $\mathrm{VO}_{5}$ square pyramids via O 4 atoms. $\mathrm{MoVAlO}_{7}$ exhibits a three-dimensional network. We note the short $\mathrm{V}-\mathrm{O} 5$ distance typical of the classical multiple bond between $\mathrm{V}^{5+}$ and oxygen in the apical position of the $\mathrm{VO}_{5}$ square pyramid, pulling $V$ above the basal square plane of O atoms (Table 1). The unexpected composition of such a crystal drove us to confirm immediately by solid-state synthesis the formation of this phase (see Experimental). A green powder was obtained and all the reflections of the X-ray powder pattern were indexed with the single-crystal data. The measured density of $\mathrm{MoVAlO}_{7}$ is in good agreement with the calculated density. The $\mathrm{MoVAlO}_{7}$ formula was then established. Following this work and knowing the molecular formula, a search was undertaken in the literature. A structure determination by X-ray powder diffraction of the same compound was published by Knorr et al. (1998), but these authors were unable to grow single crystals because the phase melted incongruently at 963 K . A comparison of both structural determinations shows a reasonable agreement of the general atomic architecture. The cell parameters are similar $[a=12.7312$ (6), $b=5.3763$ (3), $c=$ 8.1644 (3) $\AA$ and $V=558.8 \AA^{3}$ (Knorr et al., 1998)], but, of

Figure 1

course, the single-crystal study allows us to obtain very accurate bond-length and angle data. It is then readily seen that all metal-oxygen distances are in excellent agreement with the known distances in well established structures. The short V O distance of 1.586 (4) $\AA$ compares especially well with the corresponding distance in $\mathrm{V}_{2} \mathrm{O}_{5}$, i.e. 1.577 (3) $\AA$ (Enjalbert \& Galy, 1986); the V-O distance of $1.48 \AA$ found by Knorr et al. (1998) is really too short. On this basis, calculation of bond-

Figure 2
The three-dimensional network of $\mathrm{MoO}_{4}$ and $\mathrm{AlO}_{6}$ polyhedra around the $\left[\mathrm{V}_{2} \mathrm{O}_{6}\right]_{n}^{2 n-}$ infinite chains of edge-shared $\mathrm{VO}_{5}$ square pyramids.
valence sums according to Brown \& Altermatt (1985) gives a good agreement for the oxidation states of Mo, V and Al. These calculations also strengthen the fact that Knorr et al. (1998) had underestimated the uncertainties of their measurements by some $4 \sigma$. In both the $\mathrm{MoO}_{4}$ and $\mathrm{AlO}_{6}$ polyhedra, the rather regular $\mathrm{O} \cdots \mathrm{O}$ distances fluctuate between $\mathrm{O} 3 \cdots \mathrm{O} 2=2.882$ (3) $\AA$, when $\mathrm{MoO}_{4}$ connects the apices of two $\mathrm{AlO}_{6}$ octahedra, and $\mathrm{O} 4 \cdots \mathrm{O}^{v}=2.464$ (3) $\AA$, for the edge shared between the $\mathrm{VO}_{5}$ square pyramid and $\mathrm{AlO}_{6}$ [symmetry code: (v) $x, \frac{3}{2}-y, z$ ]. This last value is associated with the smallest bond angles $\left[\mathrm{O} 4-\mathrm{Al}-\mathrm{O} 4^{\mathrm{v}}=80.02(14)^{\circ}\right.$ and $\mathrm{O} 4-\mathrm{V}^{\mathrm{ii}}-\mathrm{O}^{\mathrm{v}}=77.02(13)^{\circ}$; symmetry code: (ii) $1-x, 1-y$, $-z$ ], such angles being reasonably attributed to a strong repulsion between the $\mathrm{V}^{5+}$ and $\mathrm{Al}^{3+}$ cations. The same phenomenon appears also for the edge-sharing $\mathrm{VO}_{5}$ square pyramids, the $\mathrm{O} 4 \cdots \mathrm{O} 4^{\mathrm{ii}}$ distance diminishing to 2.425 (3) $\AA$, with an $\mathrm{O} 4-\mathrm{V}-\mathrm{O} 4^{\mathrm{ii}}$ angle of $79.20(10)^{\circ}$. The $\mathrm{VO}_{5}$ square pyramids are really extremely distorted; note that the $\mathrm{O} 4 \cdots \mathrm{O} 4^{\text {vi }}$ interatomic distance is 2.915 (3) $\AA$ [symmetry code: (vi) $\left.x, \frac{1}{2}-y, z\right]$, and that the $\mathrm{V}-\mathrm{O}$ bonds to the basal 'square' plane are rather different, with $\mathrm{V}-\mathrm{O} 4=1.822$ (2) $\AA$ and $\mathrm{V}-$ $\mathrm{O} 4^{\mathrm{i}}=1.980$ (2) $\AA$ [symmetry code: (i) $1-x, y-\frac{1}{2},-z$ ]. Such distortions explain why some authors, substituting bigger cations like $\mathrm{Fe}^{3+}$ and $\mathrm{Cr}^{3+}$ for $\mathrm{Al}^{3+}$, have found a triclinic distortion of the network (Le Bail et al., 1995).

## Experimental

$\mathrm{AlVMoO}_{7}$ was prepared by direct interaction of a 2:1:1 stoichiometric mixture of $\mathrm{MoO}_{3}, \mathrm{~V}_{2} \mathrm{O}_{5}$ and $\mathrm{Al}_{2} \mathrm{O}_{3}$ (99.5\% Aldrich Chemical Company). The carefully ground mixture was introduced into an open quartz tube and heated for 24 h at 963 K . The density was determined using an Accupyc 1330 Micromeritics pycnometer.

Symmetry codes: (i) $1-x, y-\frac{1}{2},-z$; (ii) $1-x, 1-y,-z$; (iii) $1-x, \frac{1}{2}+y, 1-z$; (iv) $\frac{1}{2}+x, y, \frac{1}{2}-z ;$ (v) $x, \frac{3}{2}-y, z ;(\mathrm{vi})^{2} x, \frac{1}{2}-y, z ;(\mathrm{vii}) 1-x, 1-y, 1-z$.

The cell parameters and space group (Pnma) were clearly established. Since the cell volume was close to that of the $\mathrm{Mo}_{1+x} \mathrm{~V}_{2-x} \mathrm{O}_{8}$ phase, a rough formula of $\left[\mathrm{Mo}_{3} \mathrm{O}_{8}\right]$ was tried. In the Fourier and subsequent refinements of the three main electron-density peaks, it appeared, following the values of the displacement parameters, that one peak was surely Mo, the second V , and that the remaining peak

## inorganic compounds

was less populated in electrons. This last crystallographic site we ascribed to aluminium. The difference Fourier map gave five independent O -atom positions. Refinement of the positional and anisotropic displacement parameters gave a very good $R$ factor. The resulting formula was $\mathrm{MoVAlO}_{7}$, with $Z=4$ units per cell.

Data collection: COLLECT (Nonius, 1998); cell refinement: DENZO-SMN (Otwinowski \& Minor, 1997); data reduction: $D E N Z O-S M N$; program(s) used to solve structure: SIR92 (Altomare et al., 1994); program(s) used to refine structure: SHELXL96 (Sheldrick, 1996); molecular graphics: ORTEPIII (Burnett \& Johnson, 1996); software used to prepare material for publication: SHELXL96.

Supplementary data for this paper are available from the IUCr electronic archives (Reference: BR1347). Services for accessing these data are described at the back of the journal.
