The title complex,  $[\text{Mo}(\text{C}_5\text{H}_5)(\text{C}_6\text{H}_4\text{FO})(\text{C}_4\text{H}_{11}\text{Si})(\text{NO})]$ , is formed by reacting  $\text{CpMo}(\text{NO})(\text{CH}_2\text{SiMe}_3)_2$ , where Cp is cyclopentadienyl, with one equivalent of  $p\text{-FC}_6\text{H}_4\text{OH}$ . The complex exhibits the expected piano-stool molecular structure, with a linear nitrosyl ligand  $[\text{Mo}-\text{N}-\text{O} 168.2(2)^\circ]$  having Mo–N and N–O distances of 1.764(2) and 1.207(3) Å, respectively. The phenoxo Mo–O distance of 1.945(2) Å is suggestive of some multiple-bond character.

### Comment

Many attempts to generate molybdenum- and tungsten-alkoxo complexes in our laboratories have been unsuccessful. The standard metathetical protocol, using a metal-halide precursor with an alkali metal-alkoxide salt, often results in either decomposition or the formation of N–O bond-cleavage products (Legzdins *et al.*, 1996). An alternate procedure, namely protonation of the alkyl ligand in  $\text{CpMo}(\text{NO})(\text{CH}_2\text{SiMe}_3)_2$  by an alcohol to generate the corresponding alkoxo complex and  $\text{SiMe}_4$ , has now been found to generate a variety of new complexes in good yield. The title compound,  $\text{CpMo}(\text{NO})(\text{CH}_2\text{SiMe}_3)(p\text{-FC}_6\text{H}_4\text{O})$ , (I) (Fig. 1), has been synthesized by this method.

Compound (I) exhibits a pseudo-tetrahedral geometry around the Mo atom typical of this class of three-legged piano-stool molecules. The Mo–N–O linkage is linear  $[\text{Mo1}-\text{N1}-\text{O1} 168.2(2)^\circ]$ , with a short Mo1–N1 distance  $[1.764(2) \text{ \AA}]$

† Deceased October 27, 1998.

and a long N–O distance  $[1.207(3) \text{ \AA}]$ , relative to most other nitrosyls (Feltham & Enemark, 1981). This indicates that the nitrosyl ligand is strongly involved in  $\pi$ -back-bonding with the Mo centre. The phenoxo Mo–O distance is 1.945(2) Å, significantly longer than the W–O distances in the related complexes  $\text{Cp}^*\text{W}(\text{NO})(\text{OCH}_2\text{Ph})_2$   $[1.910(4) \text{ \AA}]$  and  $\text{Cp}^*\text{W}(\text{NO})(\text{OCMe}_3)_2$  [ $\text{Cp}^*$  is pentamethylcyclopentadienyl; 1.890(5) and 1.903(5) Å; Legzdins *et al.*, 1993], where the metal–oxygen bond has definite multiple-bond character. However, the phenoxo Mo–O distance is shorter than the W–O bonds in  $\text{Cp}^*\text{W}(\text{NO})(\text{OMe})[\eta^2\text{-O}=\text{C}(\text{Me})\text{CH}=\text{CPh}]$   $[2.001(7) \text{ \AA}]$ ; Legzdins *et al.*, 1998] and  $\text{Cp}^*\text{W}(\text{NO})(\text{OCMe}_3)[\eta^2\text{-N}(\text{CMe}_3)=\text{C}(\text{CH}_2\text{CMe}_3)]$   $[1.978(4) \text{ \AA}]$ ; Legzdins *et al.*, 1994]. The W–O bonds in these two compounds, by the nature of the  $\eta^2$ -bound co-ligands, are single bonds, which then suggests that the Mo–O link in (I) is somewhat more than a single bond. Comparison with other W and Mo complexes, namely  $\text{Cp}^*\text{W}(\text{MeCCMe})_2(\text{OPh})$   $[\text{W}-\text{O} 2.072(7) \text{ \AA}]$ ; O'Regan *et al.*, 1992],  $[\text{Cp}^*\text{W}(\text{Me})_2(\text{OC}_6\text{F}_5)]_2(\mu\text{-N}_2)$   $[\text{W}-\text{O} 2.079(8) \text{ \AA}]$ ; O'Regan *et al.*, 1990], and  $[\text{Mo}_2(\text{OPh-4-Me})_7(\text{Me}_2\text{NH})_2]^-$   $[\text{Mo}-\text{O}_{\text{terminal}} 2.03 \text{ \AA (average)}]$ ; Coffindaffer *et al.*, 1985], further supports this assumption.

### Experimental

In a Schlenk tube, under anaerobic and anhydrous conditions,  $(\eta^5\text{-C}_5\text{H}_5)\text{Mo}(\text{NO})(\text{CH}_2\text{SiMe}_3)_2$  (100 mg, 0.27 mmol) was combined with  $p$ -fluorophenol (31 mg, 0.27 mmol), and the mixture was dissolved in tetrahydrofuran (THF, 20 ml). The resulting purple solution was stirred for 3 d at room temperature, whereupon it became deep red. The THF was removed *in vacuo*, and the resulting red oil was dissolved in hexanes (30 ml) and filtered through a column of celite ( $2 \times 2 \text{ cm}$ ). The volume of this filtrate was reduced to 4 ml, and it was then cooled to 243 K overnight to induce the deposition of (I) as a dark-red powder (64 mg, 60% yield). X-ray quality crystals were grown from a concentrated hexanes solution at 243 K over a period of several weeks. IR (Nujol):  $1635 \text{ cm}^{-1}$  ( $\nu_{\text{NO}}$ ).  $^1\text{H NMR}$  (200 MHz,  $\text{C}_6\text{D}_6$ ):  $\delta$  6.81 (*t*, 2H, C–H<sub>m</sub>), 7.02 (*dd*, 2H, C–H<sub>o</sub>), 5.19 (*s*, 5H, C<sub>5</sub>H<sub>5</sub>), 2.48 (*d*, 1H, CH<sub>2</sub>SiMe<sub>3</sub>), 1.97 (*d*, 1H, CH<sub>2</sub>SiMe<sub>3</sub>), 0.17

The absorption correction was based on a three-dimensional analysis of symmetry-equivalent data and was performed along with batch scaling in a single step. The resulting transmission factors, therefore, include contributions from absorption, crystal decay, and detectable variations in beam intensity. The C—H distances are 0.98 Å.

Data collection: d\*TREK (Molecular Structure Corporation, 1996–1998); cell refinement: d\*TREK; data reduction: d\*TREK; program(s) used to solve structure: SIR97 (Altomare *et al.*, 1999); program(s) used to refine structure: TEXSAN (Molecular Structure Corporation, 1992–1997); software used to prepare material for publication: TEXSAN.

The authors thank NSERC and UBC for funding. They also thank Drs W. B. Sharp and B. O. Patrick for helpful discussions.

Supplementary data for this paper are available from the IUCr electronic archives (Reference: DA1210). Services for accessing these data are described at the back of the journal.
