(1,4,7-Trithiacyclononane)silver trifluoromethanesulfonate crystallizes in a tetrameric form from nitromethane, to give the title compound, $\left[\mathrm{Ag}_{4}\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{~S}_{3}\right)_{4}\right]\left(\mathrm{CF}_{3} \mathrm{SO}_{3}\right)_{4} \cdot 2 \mathrm{CH}_{3} \mathrm{NO}_{2}$. The complex cation consists of four $[\mathrm{Ag} L]^{+}$units ( $L$ is $1,4,7-$ trithiacyclononane), with four $\mathrm{Ag}-\mathrm{S}-\mathrm{Ag}$ bridges forming a cyclic tetramer. The almost planar $\mathrm{Ag}_{4} \mathrm{~S}_{4}$ ring takes an octagonal form.

## Comment

Recently, molecular squares and related cyclic oligomers of metal complexes constructed by self-assembly have attracted much attention in supramolecular chemistry (Fujita \& Ogura, 1996; Leininger et al., 2000). Thia-macrocyclic ligands have a tendency to form oligomeric complexes with metal ions such as $\mathrm{Ag}^{+}$(Blower et al., 1989; Blake et al., 2000). A cyclic trimer of $[\mathrm{Ag} L]^{+}$( $L$ is $1,4,7$-trithiacyclononane) was reported to be present in a crystal obtained from a reaction between $\mathrm{AgClO}_{4}$ and $L$ in methanol, i.e. $\left[\mathrm{Ag}_{3} L_{3}\right]\left[\mathrm{Ag} L_{2}\right]\left(\mathrm{ClO}_{4}\right)_{4}$ (Küppers et al., 1987). The ${ }^{1} \mathrm{H}$ NMR spectrum of this complex indicates a rapid ligand-exchange equilibrium in solution, and the possibility of another type of oligomer was considered. In this paper, we report the tetrameric structure of $[\mathrm{Ag} L]^{+}$observed in $[\mathrm{Ag} L]_{4}\left(\mathrm{CF}_{3} \mathrm{SO}_{3}\right)_{4} \cdot 2 \mathrm{CH}_{3} \mathrm{NO}_{2}$, (I). By changing the counteranion, solvent and metal-ligand ratio, it is possible to form the tetramer rather than the previously reported trimer.

The complex cation in (I) consists of four $[\mathrm{Ag} L]^{+}$units (Fig. 1), with the macrocyclic ligand $L$ coordinating to $\mathrm{Ag}^{+}$. One of the three $S$ atoms in each $[\operatorname{Ag} L]^{+}$unit acts as a bridging ligand to another $[\operatorname{Ag} L]^{+}$unit, forming an approximately octagonal skeletal structure comprised of four $\mathrm{Ag}^{+}$and four S atoms. All the angles at the corners of the $\mathrm{Ag}_{4} \mathrm{~S}_{4}$ octagon are close to $135^{\circ}$. There is a crystallographic inversion centre at
the centre of the complex cation, and therefore two nonequivalent $[\operatorname{Ag} L]^{+}$units exist.

The $\mathrm{Ag}_{4} \mathrm{~S}_{4}$ ring is almost flat, with a maximum deviation from the mean plane of $0.11 \AA$ for atom S1. It is interesting to compare (I) with the cyclic trimer, which also has a planar $\mathrm{Ag}_{3} \mathrm{~S}_{3}$ ring, with a corner angle of $c a 120^{\circ}$.

Each $\mathrm{Ag}^{+}$ion in the tetramer has a distorted tetrahedral geometry, with one short $\left[\mathrm{Ag} 1-\mathrm{S} 4^{\mathrm{i}} 2.460\right.$ (2) $\AA$ and $\mathrm{Ag} 2-\mathrm{S} 1$ 2.443 (2) $\AA$; symmetry code: (i) $-x,-y, 1-z]$ and three long [2.560 (2)-2.660 (2) A] Ag-S distances, with the shortest distance involving the bridging S atoms. These $\mathrm{Ag}-\mathrm{S}$ distances are slightly longer than normal, but similar silver complexes with $L$ have comparable $\mathrm{Ag}-\mathrm{S}$ distances (2.582.70 Á; Küppers et al., 1987; Blower et al., 1989). The shortest $\mathrm{Ag}-\mathrm{S}$ bond in each unit is tilted slightly, away from a pseudothreefold axis based on the macrocyclic ligand, and three $S$ -$\mathrm{Ag}-\mathrm{S}$ (adjacent) angles, which involve the unique $\mathrm{Ag}-\mathrm{S}$ bond, are not equal and are classified as one small [119.15 (6) and $\left.123.01(6)^{\circ}\right]$ and two large angles $\left[131.98(6)-134.47(6)^{\circ}\right]$. A similar distortion has been observed in tetrahedral $[\mathrm{Ag} L]$ moieties in the trimer (Küppers et al., 1987) and in $[\mathrm{Ag} L \mathrm{Cl}]$ (Blower et al., 1989), and the distortion in (I) is small relative to that in other complexes.

Figure 1
A view of the molecular structure of the tetrameric complex cation in (I), showing the atom-numbering scheme and $50 \%$ probability displacement ellipsoids. H atoms have been omitted for clarity.

One of the two large $\mathrm{S}-\mathrm{Ag}-\mathrm{S}$ (adjacent) angles in each unit is involved in the $\mathrm{Ag}_{4} \mathrm{~S}_{4}$ octagon, whereas in the trimer, the unique small $\mathrm{S}-\mathrm{Ag}-\mathrm{S}$ (adjacent) angle is involved in the $\mathrm{Ag}_{3} \mathrm{~S}_{3}$ ring. Concomitantly, the $\mathrm{Ag}-\mathrm{S}-\mathrm{Ag}$ angles in (I) are larger [134.02 (7) and $139.36(7)^{\circ}$ ] than that in the trimer [126.0 (1) ${ }^{\circ}$ ].

## Experimental

$[\mathrm{Ag} L]\left(\mathrm{CF}_{3} \mathrm{SO}_{3}\right)$ was synthesized according to the published method of Blower et al. (1989). A crystal of (I) was obtained by slow evaporation of a nitromethane solution of $[\mathrm{Ag} L]\left(\mathrm{CF}_{3} \mathrm{SO}_{3}\right)$.
