Colourless crystals of the title compound, bis(2-bromophenyl) disulfide, $\mathrm{C}_{12} \mathrm{H}_{8} \mathrm{Br}_{2} \mathrm{~S}_{2}$, are obtained from the reaction of 2-bromophenylmercaptan with metallic sodium and either zinc chloride or cadmium chloride in methanol. In the presence of $\mathrm{Zn}^{\mathrm{II}}$ ions, the crystals are orthorhombic (space group $P b c a$, with $Z^{\prime}=1$ ); with $\mathrm{Cd}^{\text {II }}$ ions present, the product is triclinic (space group $P \overline{1}$, with $Z^{\prime}=4$ ). Both polymorphs exhibit significant intramolecular $\mathrm{C}-\mathrm{H} \cdots \mathrm{S}$ hydrogen bonds. In the orthorhombic form, molecules are linked by intermolecular $\mathrm{C}-\mathrm{H} \cdots \mathrm{Br}$ hydrogen bonds, while in the triclinic form, molecules exhibit $\mathrm{Br} \cdots \mathrm{Br}$ contacts.

## Comment

The electronic and structural properties of transition and main group metal complexes coordinated by S-donor atoms have attracted intense research interest over the past 30 years

(I)
(Kasper \& Interrante, 1976; Kobayashi et al., 1982; Pullen et al., 1998; Kie-Moon \& Holm, 2001). Although some studies have appeared describing the behaviour of the disulfide group as a donor (Valde et al., 1983; Matsubayashi \& Yokozawa, 1990; Oshio, 1993; Kobayashi et al., 1990), it has not been subjected to such detailed study as a number of other donor groups (Balch et al., 1968; Gray, 1966; Schrauzer \& Mayweg, 1966). This neglect is in part because the disulfide group tends to give bridged or polymeric metal complexes, which are extremely insoluble and are accordingly difficult to characterize or study. We report here the structures of two polymorphs of bis(2-bromophenyl) disulfide, isolated during attempts to synthesize zinc(II) or cadmium(II) complexes of the ligand. There are no significant differences in the bond lengths observed for the two polymorphs (Figs. 1 and 2, and

Tables 1 and 3). The substituents are essentially coplanar with their respective rings, giving molecules in which all the atoms lie in two planes. The dihedral angle between the planes of the two phenyl rings in the orthorhombic form is 83.34 (9) ${ }^{\circ}$, while an average value of $84.90(2)^{\circ}$ is observed for the triclinic form. The values of the $\mathrm{S} 11-\mathrm{S} 21-\mathrm{C} 21-\mathrm{C} 22, \mathrm{~S} 11-\mathrm{S} 21-$ C21-C26, S21-S11-C11-C12 and S21-S11-C11-C16 torsion angles in the orthorhombic form $[-174.69(14)$, $7.46(19),-172.68(14)$ and $8.33(18)^{\circ}$, respectively] are slightly different from the corresponding mean angles in the triclinic system $\left[-169.9\right.$ (2), 11.1 (2), -169.2 (2) and 13.5 (2) ${ }^{\circ}$, respectively]. The orthorhombic form crystallizes with one

independent molecule in each asymmetric unit (Fig. 1), while in the triclinic form there are four (Fig. 2). In both polymorphs, the phenyl rings participate in significant intramolecular $\mathrm{C}-\mathrm{H} \cdots \mathrm{S}$ interactions, with average $\mathrm{H} \cdots \mathrm{S}$ distances of 2.69 and $2.72 \AA$ (for the orthorhombic and triclinic forms, respectively). The crystal packing for the orthorhombic form shows repulsion between Br atoms, leading to a staggered arrangement of Br atoms in adjacent molecules. This staggered conformation involves intermolecular $\mathrm{C}-\mathrm{H} \cdots \mathrm{S}$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{Br}$ hydrogen bonds that are not present in the triclinic form (Fig. 3 and Table 2). The orthorhombic form exhibits mean $\mathrm{H} \cdots \mathrm{S}$ and $\mathrm{H} \cdots \mathrm{Br}$ distances of 2.98 and $3.04 \AA$, respectively. In contrast, the triclinic form shows eclipsed dispositions for the Br atoms in different molecules (Fig. 4),

Figure 3
The packing arrangement in the orthorhombic form, (I), viewed along $b$. Hydrogen bonds are indicated by dashed lines.

Figure 4
The packing arrangement in the triclinic form, (II), viewed along $c$. Hydrogen bonds and $\mathrm{Br} \cdots \mathrm{Br}$ contacts are indicated by dashed lines.
which minimizes the intermolecular hydrogen bonding predominant in the orthorhombic form (Table 4). As a result of this eclipsed conformation between adjacent Br atoms and the large covalent radius of these atoms $(1.14 \AA)$, an accumulation of charge exists around each Br atom. The higher electron density around the Br atoms produces closer [3.770 (9) $\AA$ ] repulsive contacts between them (Table 5), giving rise to less efficient packing, which can be seen by comparing the cell volumes [2480.4 (6) and 2531.4 (8) $\AA^{3}$ ] and crystal densities ( 2.014 and $1.974 \mathrm{Mg} \mathrm{m}^{-3}$ ) for the orthorhombic and triclinic forms.

## Experimental

The title compound was prepared by refluxing a methanol solution ( 15 ml ) of 2-bromophenylmercaptan ( 2 mmol ) in the presence of metallic sodium ( 1 g ) and either $\mathrm{ZnCl}_{2}$ or $\mathrm{CdCl}_{2}$ ( 1 mmol ). After refluxing for 4 h at 338 K , the volume of the solution was concentrated to 5 ml and maintained at 278 K for a week, leading to the formation of colourless columns $\left(\mathrm{ZnCl}_{2}\right)$ or plates $\left(\mathrm{CdCl}_{2}\right)$. IR and NMR spectra for both crystals correspond to the title compound. Analysis found for the orthorhomic form: C 38.15, H 2.38 , S $17.22 \%$; found for the triclinic form: C 38.15, H $2.30, \mathrm{~S} 16.98 \%$; calculated for $\mathrm{C}_{12} \mathrm{H}_{8} \mathrm{Br}_{2} \mathrm{~S}_{2}$ : C 38.30, H 2.13, S 17.02\%.
