Unusually large and good-quality single crystals of the synthetic trioctahedral mica $\mathrm{KFe}_{3}^{2+}\left(\mathrm{Al}_{0.26} \mathrm{Fe}_{0.76}^{3+} \mathrm{Si}_{3}\right) \mathrm{O}_{10}(\mathrm{OH})_{2}$ [potassium triiron(II) aluminasilaferrate(III) decaoxide dihydroxide] have been grown hydrothermally. X-ray diffraction data measured at 270 and 100 K have been used to refine the crystal structure, including the positions of the H atoms. This synthetic mica is similar to annite, $\mathrm{KFe}_{3} \mathrm{AlSi}_{3} \mathrm{O}_{10}(\mathrm{OH})_{2}$, and crystallizes with the same monoclinic $C 2 / m$ symmetry. No phase transition has been observed down to 100 K . At low temperature, the ditrigonal distortion of the mica structure increases markedly, while the octahedral and tetrahedral bond lengths tend to decrease and increase, respectively. A detailed comparison of structural parameters in various Fe-rich micas is presented.

## Comment

Trioctahedral micas, $X Y_{3} Z_{4} \mathrm{O}_{10}(\mathrm{OH})_{2}$ (where $X$ is an interlayer cation, $Y$ is an octahedral cation and $Z$ is a tetrahedral cation), are widely occurring rock-forming minerals. Their crystal chemistry is complex as they can accommodate a large variety of cations into their structure. Systematic structural and spectroscopic studies of synthetic micas are thus important in order to obtain a more complete understanding of the crystal chemical variations with changing chemical composition.

Natural trioctahedral micas have been investigated intensively by single-crystal X-ray diffraction methods, and a recent review on mica crystal chemistry is found in Brigatti \& Guggenheim (2002). However, studies on Fe-rich micas are rare. The Fe -bearing mica closest to the ideal composition of the mineral annite, $\mathrm{KFe}_{3} \mathrm{AlSi}_{3} \mathrm{O}_{10}(\mathrm{OH})_{2}$, is that studied by Redhammer \& Roth (2002), with a composition of $\left(\mathrm{K}_{0.94} \mathrm{Na}_{0.07}\right)\left(\mathrm{Fe}_{2.25}^{2+} \mathrm{Fe}_{0.28}^{3+} \mathrm{Mn}_{0.18} \mathrm{Mg}_{0.07} \mathrm{Ti}_{0.08}\right)\left(\mathrm{Al}_{0.98} \mathrm{Fe}_{0.19}^{3+} \mathrm{Si}_{2.83}\right)-$ $\mathrm{O}_{10}\left(\mathrm{OH}_{1.85} \mathrm{~F}_{0.15}\right)$. In addition to natural trioctahedral micas, Redhammer \& Roth (2002) also studied a variety of synthetic samples with various octahedral contents but containing no tetrahedral ferric iron. Other structural studies of tetra-
ferrimicas have been carried out for $\mathrm{CsFe}_{3}\left(\mathrm{Fe}^{3+} \mathrm{Si}_{3}\right) \mathrm{O}_{10}(\mathrm{OH})_{2}$ (Mellini et al., 1996; Comodi et al., 1999) and $\mathrm{RbFe}_{3}\left(\mathrm{Fe}^{3+}\right.$ $\left.\mathrm{Si}_{3}\right) \mathrm{O}_{10}(\mathrm{OH})_{2}$ (Comodi et al., 2003). Donnay et al. (1964) were the first workers to refine the structure of a synthetic tetraferriannite (TFA), $\mathrm{KFe}_{3}\left(\mathrm{Fe}^{3+} \mathrm{Si}_{3}\right) \mathrm{O}_{10}(\mathrm{OH})_{2}$, from film data. However, a complete refinement was not possible and no anisotropic displacement parameters were refined, nor were the H atoms located. To date, no data are available for K containing trioctahedral micas containing Fe exclusively in the octahedral sheet. In the course of our investigations on micas of the formula $\mathrm{KFe}_{3}\left(\mathrm{Al}_{1-x} \mathrm{Fe}_{x}^{3+} \mathrm{Si}_{3}\right) \mathrm{O}_{10}(\mathrm{OH})_{2}$, unusually large (about $500 \mu \mathrm{~m}$ long) and good-quality single crystals of the title compound, (I), were obtained: its crystal structures at 100 and 270 K are described here and compared with the structures of the near-end-member annite (Redhammer \& Roth, 2002) and Rb and Cs tetraferriannites (Comodi et al., 1999, 2003).

Fig. 1 depicts part of the structure the title compound. Other polyhedral representations of the mica structure may be found in the literature (e.g. Brigatti \& Guggenheim, 2002). The discussion below refers to the structure at 270 K .

The octahedral sheet of the structure of (I) contains two different $M 1$ and $M 2$ sites which each carry an OH group. The H atom is located 0.87 (4) $\AA$ from atom O4 and the $\mathrm{O}-\mathrm{H}$ bond is not exactly perpendicular to the (001) plane, but slightly inclined along the $a$ axis towards the centre of the ring defined by six $T \mathrm{O}_{4}$ tetrahedra (with $T=\mathrm{Si}^{4+}, \mathrm{Al}^{3+}, \mathrm{Fe}^{3+}$ ). The average $M 1-\mathrm{O}$ bond in (I) [2.119 (1) Å; Table 2] is similar to that in the end-member tetraferriannite [2.11 (1) $\AA$; Donnay et al., 1964]. The average $M 1-\mathrm{O}$ bond length increases with the size of the interlayer cation (Table 2), as a result of the expansion of the unit cell, not only along [001] (which is most sensitive to changes in the interlayer chemistry), but also within the (001) plane. The bond-length distortion (BLD in Table 2) of the $M 1$ octahedron is small and similar to that found for annite and the Rb and Cs tetraferriannites. However, the edge-length ratio ( $e_{\mathrm{u}} / e_{\mathrm{s}}$; Toraya, 1981) and the octahedral-angle variance (OAV; Robinson et al., 1971) both indicate a significant angular distortion of the $M 1$ site, as does the octahedral flattening angle $(\psi)$, which is distinctly larger than its ideal value of $54.73^{\circ}$. Replacing K in the interlayer by Rb or Cs increases the octahedral flattening and reduces the thickness of the octahedral sheet (Table 2). The polyhedral distortion of the $M 2$ site is similar to that of $M 1$. This is a general feature of all trioctahedral micas, except those containing octahedrally coordinated $\mathrm{Al}^{3+}$ (Redhammer \& Roth, 2002). As observed for $M 1$, the average $M 2-\mathrm{O}$ bond length is somewhat larger than in synthetic tetraferriannite (Donnay et al., 1964).

The average $T-\mathrm{O}$ bond length in the title compound [1.676 (1) $\AA$ ] is somewhat shorter than in the Rb or Cs tetraferriannites, or tetraferriphlogopite [1.680 (2) Å; Brigatti et al., 1996]. This is related to the presence of tetrahedral $\mathrm{Al}^{3+}$ in addition to $\mathrm{Si}^{4+}$ and $\mathrm{Fe}^{3+}$. It has been noted by Brigatti et al. (1996) that the substitution of tetrahedral $\mathrm{Al}^{3+}$ by larger cations, such as $\mathrm{Fe}^{3+}$, produces more regular tetrahedra. This effect is also observed here, as shown by the smaller BLD and
tetrahedral angle variance (TAV) (Table 2). As a result of the $\mathrm{Fe}^{3+} / \mathrm{Al}^{3+}$ tetrahedral substitution, the dimensional misfit between the octahedral and tetrahedral sheets increases but is compensated for by an increase of the tetrahedral ringdistortion angle ( $\alpha$ in Table 2). This distortion of the tetrahedral sheet directly influences the coordination geometry of the interlayer cation. Whereas the inner and outer $\mathrm{K}-\mathrm{O}$ bond lengths are similar when the ditrigonal distortion is small (e.g. near-end-member annites, Rb-TFA and Cs-TFA), the difference between the $\mathrm{K}-\mathrm{O}$ distances increases with increasing tetrahedral rotation, $\alpha$ (Table 2). Due to the expansion of the octahedral sheet in the (001) plane of Rb- and Cs-TFA, the tetrahedral ring has a nearly ideal hexagonal geometry in these structures.

At room temperature, the lattice parameters of (I) are larger than those of pure annite (e.g. Redhammer et al., 1993; Redahmmer \& Roth, 2002) but slightly smaller than those of pure tetraferriannite $[a=5.4354$ (6) $\AA, b=9.4186$ (7) $\AA, c=$ 10.3449 (5) $\AA$ and $\beta=100.121$ (14) ${ }^{\circ}$; Redhammer et al., 2004]. These differences are attributed to the different composition of the tetrahedral sheet. Upon cooling from 270 to 100 K , the lattice parameters decrease significantly and yield linear thermal expansion coefficients of $11.1 \times 10^{-6}, 10.8 \times 10^{-6}$ and $21.6 \times 10^{-6} \mathrm{~K}^{-1}$ for the $a, b$ and $c$ axes, respectively. These coefficients are similar to those in near-end-member phlogopite, viz. 8.6, 7.5 and 18.1 (all $\times 10^{-6} \mathrm{~K}^{-1}$; Russell \& Guggenheim, 1999). The thermal expansion along $\mathbf{c}$ is twice as large as that within the (001) plane. The [001] direction corresponds to the stacking of the negatively charged $2: 1$

Figure 1
Part of the $\mathrm{KFe}_{3}\left(\mathrm{Al}_{0.24} \mathrm{Fe}_{0.76}^{3+}\right) \mathrm{Si}_{3} \mathrm{O}_{10}(\mathrm{OH})_{2}$ structure at 270 K , with displacement ellipsoids drawn at the $90 \%$ probability level. [Symmetry codes: (i) $x-\frac{1}{2}, \frac{1}{2}-y, z$; (ii) $x,-y, z$; (iii) $\frac{1}{2}+x, \frac{1}{2}-y, z$; (iv) $1+x, y, z$; (v) $2-x, y, 1-z$; (vi) $1-x, y, 1-z ;$ (vii) $\frac{3}{2}-x, \frac{1}{2}-y, 1-z ;$ (viii) $1-x,-y$, $1-z$.
layers and is the direction most affected by the thermal motion of the interlayer $\mathrm{K}^{+}$cation.

In addition to the shortening of the unit-cell parameters, the most pronounced changes upon cooling from 270 to 100 K are observed for the interlayer region of the structure. The average $\mathrm{K}-\mathrm{O}_{\text {inner }}$ bond shortens, while the average $\mathrm{K}-\mathrm{O}_{\text {outer }}$ bond lengthens, corresponding to an increase of the ditrigonal distortion (Table 2). This increase, as measured by a larger rotation angle $\alpha$, is related to the different thermal expansion of the octahedral and tetrahedral sheets, whereby the average

Figure 2
Polyhedral representation of the structure of $\mathrm{KFe}_{3}\left(\mathrm{Al}_{0.24} \mathrm{Fe}_{0.76}^{3+}\right) \mathrm{Si}_{3} \mathrm{O}_{10^{-}}$ $(\mathrm{OH})_{2}$ at 270 K in a projection along the $b$ axis, showing the 2:1 layer and its interconnection by the interlayer cations.
$M-\mathrm{O}$ bond lengths tend to decrease at low temperature while the average $T-\mathrm{O}$ bond lengths tend to increase (Table 2). Although the changes in bond length $(0.003 \AA)$ are only slightly larger than the standard uncertainty $(0.001 \AA)$, an equivalent trend was observed for a near-end-member phlogopite, $\mathrm{KMg}_{3} \mathrm{AlSi}_{3} \mathrm{O}_{10}(\mathrm{OH})_{2}$, in which the average $T-\mathrm{O}$ bond length decreased by 0.004 A upon heating from 293 to 873 K (Russell \& Guggenheim, 1999). The decrease in the tetrahedral angle $\tau$ upon cooling (Table 2) indicates that the tetrahedra are slightly elongated along the $c$ axis at high temperature and compressed at low temperature.

The anisotropic atomic displacement parameters (ADPs) are also affected by cooling. Atoms O 1 and O 2 , which are shared between tetrahedra, show larger ADPs than atoms O3 and O4, which bridge tetrahedra and octahedra (Fig. 1). This suggests that the latter are more rigidly bonded than the former. The interlayer $\mathrm{K}^{+}$cation shows a more anisotropic displacement than the octahedral cations, while the displacement of the tetrahedral cation is nearly isotropic. This behaviour is generally observed in all trioctahedral micas. Upon cooling to 100 K , the displacement decreases by $\sim 47 \%$ for the K site, $\sim 38 \%$ for the $M$ sites, $26 \%$ for the $T$ site and $30 \%$ for the O sites. Only minor changes are observed in the ADP max/ min ratios, indicating that there is no significant change in the anisotropic behaviour of the atoms.

## Experimental

Single crystals of the title compound were synthesized under hydrothermal conditions using temperature-gradient experiments in 5 cm long Au tubes at 973 K under a hydrostatic pressure of 0.4 GPa . Stoichiometric amounts of $\mathrm{K}_{2} \mathrm{CO}_{3}, \mathrm{Fe}_{2} \mathrm{O}_{3}, \mathrm{Al}_{2} \mathrm{O}_{3}$ and $\mathrm{SiO}_{2}$ were carefully ground to a homogeneous fine-grained powder in an agate mortar under alcohol. This powder was the starting material for the synthesis. The oxygen fugacity during the experiment was determined by the high-pressure vessel and was close to the nickel/nickel-oxide solid-state buffer. A small number of unusually large mica single crystals with a nearly prismatic habit formed at the 'cold' end of the Au capsule. This crystal shape is unusual, as micas normally form thin flakes.

Symmetry codes: (i) $1+x, y, z$; (ii) $\frac{1}{2}+x, \frac{1}{2}-y, z$; (iii) $x-\frac{1}{2}, \frac{1}{2}-y, z$; (iv) $1-x,-y,-z$; (v) $x,-y, z$; (vi) $1-x,-y, 1-z$; (vii) $1-x, y, 1-z$; (viii) $\frac{2^{2}}{2}-x, \frac{1}{2}-y, 1-z$.

Several crystals were examined before the full data collection was carried out. Analysis of the systematic absences confirmed the $C$-centred space group, identifying the polytype as $1 M$. The composition of the tetrahedral site was determined by assuming an ideal Si content (0.75) and refining variable amounts of $\mathrm{Al}^{3+}(x)$ and $\mathrm{Fe}^{3+}$ $\left(\frac{1}{4}-x\right)$. The refined composition is close to that determined by microprobe analysis of fine-grained mica products of the same experiment (Redhammer et al., 2004). Mellini et al. (1996) noted residual electron-density maxima located at $b / 3$ from the original atom positions and interpreted them as due to faults in the stacking sequence along the [001] direction. No significant residual electron

Table 3
Structural parameters for selected Fe-bearing trioctahedral $1 M$ micas.
Bond-length distortion (BLD) $=(100 / n) \sum_{i=1}^{n}\left\{\left[(X-\mathrm{O})_{i}-(<X-\mathrm{O}>)\right] /(<X-\right.$ $\mathrm{O}>)$ ), with $n=$ number of bonds, $(X-\mathrm{O})_{\mathrm{i}}=$ central cation-to-oxygen length and $\langle X-\mathrm{O}\rangle=$ average cation-oxygen bond length (Renner \& Lehmann, 1986); edge-length distortion (ELD) $=(100 / n) \sum_{i=1}^{n}\left\{\left[(\mathrm{O}-\mathrm{O})_{i}-(\langle\mathrm{O}-\mathrm{O}\rangle)\right] /\right.$ $(<\mathrm{O}-\mathrm{O}\rangle)\}$, with $n=$ number of edges, $(\mathrm{O}-\mathrm{O})_{i}=$ polyhedron edge length and $<\mathrm{O}-\mathrm{O}>=$ average polyhedron edge length (Renner \& Lehmann, 1986); octahedral angle variance $(\mathrm{OAV})=\sum_{i=1}^{n}\left(\theta_{i}-90\right)^{2} / 11$ (Robinson et al., 1971); octahedral flattening angle $\psi: \cos \psi=t_{\text {oct }} / 2 d_{\text {oct }}$, with $d_{\text {oct }}=$ average $M-\mathrm{O}$ distance and $t_{\mathrm{oct}}=$ octahedral sheet thickness, $t_{\mathrm{oct}}=2\left(\frac{1}{2}-\left[2\left(z_{\mathrm{O} 3}-z_{\mathrm{O} 4}\right) /\right.\right.$ 3] $\} c \sin \beta$; unshared edge $e_{\mathrm{u}}$ /shared edge $e_{\mathrm{s}}$ (Toraya, 1981); tetrahedral angle variance (TAV) $=\sum_{i=1}^{n}\left(\theta_{i}-109.47\right)^{2} / 5$ (Robinson et al., 1971); $\tau=$ mean of the three $\mathrm{O}_{\text {basal }}-T-\mathrm{O}_{\text {apex }}$ angles; $\alpha=$ ditrigonal distortion of the tetrahedral sheet with $\tan \alpha=4 \times 3^{\frac{1}{2}}\left(\frac{1}{4}-y_{01}\right)$.

$\dagger$ Natural annite (Redhammer \& Roth, 2002). $\ddagger$ Tetraferriannite at 270 K (this work). § Tetraferriannite at 100 K (this work). - Rb tetraferriannite (Comodi et al., 2003). $\dagger \dagger$ Cs tetraferriannite (Comodi et al., 1999).
density was observed in the case of the present crystals, including those with a large dimension along $c$. Structure refinements carried out on two additional crystals from the same synthesis batch yielded
identical results to those presented here, within one standard uncertainty.

For compound (I) at both temperatures, data collection: $X$ - $A R E A$ (Stoe \& Cie, 2002); cell refinement: X-AREA; data reduction: $X-A R E A ; \operatorname{program}(\mathrm{s})$ used to solve structure: SHELXS97 (Sheldrick, 1997); program(s) used to refine structure: SHELXL97 (Sheldrick, 1997); molecular graphics: DIAMOND (Brandenburg \& Berndt, 1999); software used to prepare material for publication: WinGX (Farrugia, 1999).

GJR thanks the Austrian Academy of Science for financial support via an APART (Austrian Programme for Advanced Research and Technology) scholarship during 2000-2003, and the Austrian Science Foundation (FWF) for financial support through grant No. R33-N10. The thorough review of an anonymous referee and the kind help of Jacques Barbier in improving the impact of the paper are greatly acknowledged.

Supplementary data for this paper are available from the IUCr electronic archives (Reference: BC1034). Services for accessing these data are described at the back of the journal.
