The title compound,  $C_{15}H_{16}Cl_4N_5O_2P_3$ , is a cyclophosphazenic lariat (PNP-pivot) ether with a spiro-cyclic 12-membered macrocyclic ligand containing two ether O and two N atoms; the phosphazene ring is nearly planar. In the macrocyclic ring, there is a four-center (trifurcate)  $N-H\cdots O/N-H\cdots N$  hydrogen bond. The relative inner-hole size of the macrocycle is estimated as approximately 0.95 Å.

### Comment

$N_3P_3Cl_6$  is the standard compound for trimeric phosphazene derivatives. It has potential use in the preparation of novel small organocyclophosphazenes and high polymeric phosphazene derivatives with inorganic backbones and various side groups (Allcock *et al.*, 1992; Olshavsky & Allcock, 1995; Hökelek *et al.*, 1996).

The structures of organic, inorganic or organometallic side groups are highly effective in determining the specific physical and chemical properties of phosphazene polymers (Allcock *et al.*, 1987, 1996). Some of the polymeric phosphazene derivatives may be useful as high refractive index glasses (Olshavsky & Allcock, 1995), ferroelectric and non-linear optical polymers (Dembek *et al.*, 1991; Allcock *et al.*, 1995), liquid crystalline materials (Allcock & Kim, 1991) and biomedical materials (Cohen *et al.*, 1990).

The crystal structure of  $N_3P_3Cl_6$  (Bullen, 1971) and of a few of its derivatives with bulky phenoxy groups have been reported.

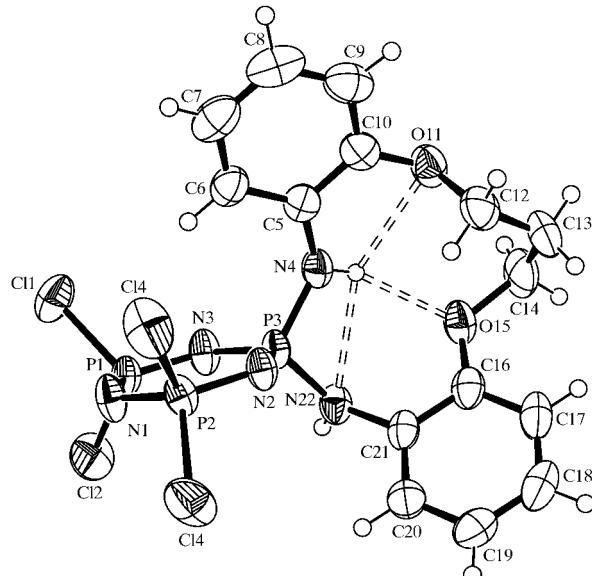

Figure 1

An ORTEP-3 (Farrugia, 1997) drawing of the title molecule with the atom-numbering scheme. Displacement ellipsoids are drawn at the 50% probability level and broken lines indicate hydrogen bonds.

In the literature, there are a limited number of reports on the structures of the cyclophosphazenic lariat (PNP-pivot) ethers (Yıldız *et al.*, 1999; Brandt *et al.*, 1999, 2001; Bartsch *et al.*, 2002).

Two kinds of compounds are expected to be formed from the reaction of  $N_3P_3Cl_6$  with propylene glycol bis(2-amino-phenyl ether), namely spiro- and ansa-cyclophosphazenic lariat ethers. However, only the spiro-cyclic 12-membered macrocyclic ligand, (I), has been isolated, which is a new class of macrocyclic multidentate ligand where the macrocycle and the phosphazene rings are linked, forming a novel structure.

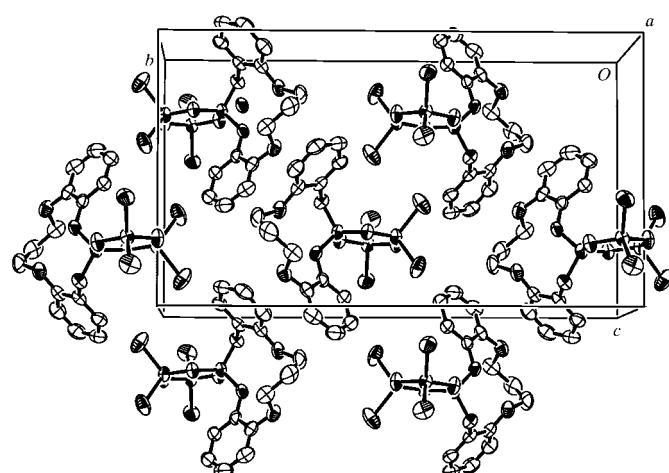

The title compound, (I), may be a potential ion-selective reagent for lithium and transition metal cations. The structure determination of (I) was carried out in order to estimate the inner-hole size of the macrocyclic ring and to understand the influence of the highly hindered macrocyclic ring on the structure of the cyclic trimeric phosphazene. The macrocyclic ring (Fig. 1) includes two ether O and two N atoms. The intramolecular distances  $P_3\cdots C_{13}$  [5.222 (3) Å],  $C_{10}\cdots C_{21}$  [5.123 (4) Å],  $N_4\cdots O_{11}$  [2.730 (4) Å],  $N_4\cdots O_{15}$  [2.891 (4) Å],  $N_{22}\cdots O_{11}$  [4.712 (4) Å] and  $N_{22}\cdots O_{15}$  [2.729 (4) Å] may indicate the inner-hole size of the macrocyclic ring. The least-squares plane defined by atoms  $N_4$ ,  $N_{22}$ ,  $O_{11}$  and  $O_{15}$  has maximum deviations of 0.145 (2), -0.122 (2), -0.080 (2) and 0.070 (2) Å, respectively.

The relative inner-hole size of the macrocyclic ring is estimated as approximately 0.95 Å, taking into account the best least-squares plane defined by atoms  $N_4$ ,  $N_{22}$ ,  $O_{11}$  and  $O_{15}$ , and the trifurcate hydrogen bond in the macrocycle, using the ‘modified covalent radii’ of  $Nsp^2$  (0.66 Å) and  $Osp^3$  (0.76 Å) atoms (Goodwin *et al.*, 1982; Adam *et al.*, 1983; Drummond *et al.*, 1982). The macrocycle is contracted by a trifurcate  $N-H\cdots O/N-H\cdots N$  hydrogen bond, with the central part of the macrocycle being occupied by the trifurcate hydrogen bond.

The phosphazene ring is nearly planar. The P—N bonds are in the range 1.552 (2)–1.604 (2) Å and have a regular variation with the distance from atom P3 in the ring: P3—N3  $\simeq$  P3—N2 > P1—N3  $\simeq$  P2—N2 < P1—N1  $\simeq$  P2—N1. The P—N bonds of the phosphazene ring (Table 1) have double-bond character. On the other hand, the P—N bonds of the macrocycle are near the lower limit of the single-bond-length range. In phosphazene derivatives, the P—N single and double bonds are generally in the ranges 1.628–1.691 and 1.571–1.604 Å, respectively (Allen *et al.*, 1987). The shortening in the P—N bonds of the macrocycle may be due to electron release from the N atoms of the macrocycle to the phosphazene ring.

In the phosphazene ring, for the angles nearest the macrocycle, *viz.* endocyclic  $\alpha$ (N2—P3—N3) of 114.6 (1) $^\circ$  and exocyclic  $\alpha'$ (N4—P3—N22) of 103.3 (1) $^\circ$ ,  $\alpha$  is decreased while  $\alpha'$  is increased with increasing electron supply and repulsions of the substituents relative to the  $\text{N}_3\text{P}_3\text{Cl}_6$  standard compound. The  $\beta$ (P2—N2—P3) and  $\beta$ (P1—N3—P3) angles change considerably and seem to increase with increasing electron supply to the  $\text{N}_3\text{P}_3$  ring (Kılıç *et al.*, 1996). In (I),  $\beta$ (P2—N2—P3)  $\simeq$   $\beta$ (P1—N3—P3) >  $\beta$ (P1—N1—P2); the  $\alpha$  angle is significantly smaller and the  $\alpha'$  angle a little larger than the corresponding values [118.3 (2) and 101.2 (1) $^\circ$ , respectively] in the  $\text{N}_3\text{P}_3\text{Cl}_6$  standard compound, but the  $\beta$  angles [123.3 (1) and 123.2 (1) $^\circ$ ] are larger than the reported value [121.4 (3) $^\circ$ ] in the  $\text{N}_3\text{P}_3\text{Cl}_6$  standard compound (Bullen, 1971).

On the other hand, the  $\alpha$  angle is larger than the corresponding value of 109.2 (4) $^\circ$  in  $[\text{N}_3\text{P}_3\text{Cl}_4(\text{NPPH}_3)_2]$  (Fincham *et al.*, 1986), but not significantly different from the values of 114.4 (1) and 114.5 (2) $^\circ$  in  $[\text{N}_3\text{P}_3\text{Cl}_5(\text{NPPH}_3)]$  (Fincham *et al.*, 1986) and  $[\text{N}_3\text{P}_3\text{Cl}_4\text{Ph}(\text{PPh}_2)]$  (Allcock *et al.*, 1990), and a little smaller than the  $\alpha$  values of 115.8 (1), 115.1 (1) and 115.8 (1) $^\circ$  in  $\text{N}_3\text{P}_3\text{Cl}_2[(\text{OC}_6\text{H}_3)(\text{NO}_2)\text{CH}_2(\text{OC}_6\text{H}_3)(\text{NO}_2)(\text{Ph}_2)]$  (Hökelek *et al.*, 2001),  $[\text{N}_3\text{P}_3\text{Cl}_5(\text{OC}_6\text{H}_2-2,6-\text{'Bu}_2-4-\text{Me})]$  (Hökelek *et al.*, 1999) and  $[\text{N}_3\text{P}_3\text{Cl}_5(\text{OC}_6\text{H}_2-2,4,6-\text{'Bu}_3)]$  (Kılıç *et al.*, 1996), respectively. In (I), the macrocycle releases electrons to the  $\text{N}_3\text{P}_3$  ring, as seen for one of the NPPH<sub>3</sub> groups in

**Figure 2**  
Packing diagram of (I).

$[\text{N}_3\text{P}_3\text{Cl}_4(\text{NPPH}_3)_2]$  (Fincham *et al.*, 1986); the NPPH<sub>3</sub> group is known to be a very strong electron-releasing group in phosphazene chemistry.

In the macrocycle, there is a four-center (trifurcate) N—H···O/N—H···N hydrogen bond (Table 2). The Cremer & Pople (1975) total puckering amplitude for the macrocycle is  $Q_T = 1.602$  (4) Å and the torsion angles (Table 1) have the sequence  $-ap$ ,  $+ap$ ,  $+sp$ ,  $-sc$ ,  $+ap$ ,  $-sc$ ,  $-sc$ ,  $-sc$ ,  $+ap$ ,  $+sp$ ,  $-ac$  and  $+sc$  ( $sp$  denotes synperiplanar,  $sc$  synclinal and  $ap$  antiperiplanar), corresponding to the P3—N4, ..., N22—P3 bond sequence. The conformation of the macrocyclic ring is conditioned by the three hydrogen bonds (Fig. 1) and the planarity of the two benzo-fused N—C—C—O systems.

As can be seen from the packing diagram (Fig. 2), the macrocyclic rings are elongated approximately parallel to the (0  $\frac{1}{2}$  1) planes and stacked along the  $a$  axis. Dipole–dipole and van der Waals interactions are also effective in the molecular packing.

## Experimental

A solution of  $\text{N}_3\text{P}_3\text{Cl}_6$  (2.5 g, 7.18 mmol) in acetonitrile (100 ml) was added dropwise to a mixture of propylene glycol bis(2-aminophenyl ether) (1.85 g, 7.20 mmol) and  $\text{NEt}_3$  (3.63 g, 35.9 mmol) in acetonitrile (50 ml) at 263 K over a period of 1 h. After the mixture had been allowed to reach ambient temperature, stirring was continued for 26 h with argon being passed over the reaction mixture. The precipitated amine hydrochloride was filtered off and the solvent was evaporated under reduced pressure. The residue was dissolved in benzene (20 ml) and subjected to column chromatography (silica gel 40 g, eluting with benzene) and crystallized from benzene–dichloromethane (2:1) (m.p. 467 K; yield 2.53 g, 66%).

## Crystal data

$C_{15}\text{H}_{16}\text{Cl}_4\text{N}_5\text{O}_2\text{P}_3$	$D_x = 1.618 \text{ Mg m}^{-3}$
$M_r = 533.04$	Mo $K\alpha$ radiation
Monoclinic, $P2_1/n$	Cell parameters from 25 reflections
$a = 7.7094$ (6) Å	$\theta = 10\text{--}15^\circ$
$b = 22.404$ (2) Å	$\mu = 0.78 \text{ mm}^{-1}$
$c = 12.6960$ (14) Å	$T = 293$ (2) K
$\beta = 93.751$ (7) $^\circ$	Block, colorless
$V = 2188.2$ (4) Å <sup>3</sup>	$0.40 \times 0.25 \times 0.25$ mm
$Z = 4$	

## Data collection

Enraf-Nonius CAD-4 diffractometer	$\theta_{\max} = 26.3^\circ$
Non-profiled $\omega$ scans	$h = 0 \rightarrow 9$
4703 measured reflections	$k = -27 \rightarrow 0$
4385 independent reflections	$l = -15 \rightarrow 15$
3132 reflections with $I > 2\sigma(I)$	3 standard reflections frequency: 120 min
$R_{\text{int}} = 0.022$	intensity decay: 1%

## Refinement

Refinement on $F^2$	$w = 1/[\sigma^2(F_o^2) + (0.0525P)^2 + 1.1216P]$
$R[F^2 > 2\sigma(F^2)] = 0.038$	where $P = (F_o^2 + 2F_c^2)/3$
$wR(F^2) = 0.110$	$(\Delta/\sigma)_{\max} < 0.001$
$S = 1.02$	$\Delta\rho_{\max} = 0.39 \text{ e } \text{\AA}^{-3}$
4385 reflections	$\Delta\rho_{\min} = -0.38 \text{ e } \text{\AA}^{-3}$
322 parameters
