The title complex,  $2\text{C}_5\text{H}_7\text{N}_2^+\cdot\text{C}_4\text{H}_2\text{O}_4^{2-}\cdot\text{C}_4\text{H}_4\text{O}_4$ , contains cyclic eight-membered hydrogen-bonded rings involving 2-aminopyridinium and fumarate ions. The fumaric acid molecules and fumarate ions lie on inversion centers and are linked into zigzag chains by  $\text{O}—\text{H}\cdots\text{O}$  hydrogen bonds. The dihedral angle between the pyridinium ring and the hydrogen-bonded fumarate ion is  $7.60$  ( $4^\circ$ ). The fumarate anion is linked to the pyridinium cations by intermolecular  $\text{N}—\text{H}\cdots\text{O}$  hydrogen bonds. The heterocycle is fully protonated, thus enabling amine–imine tautomerization.

## Comment

The title complex was obtained from the reaction of 2-aminopyridine (used in the manufacture of pharmaceuticals, hair dyes and other dyes) and fumaric acid. Hydrogen bonding plays a key role in molecular recognition (Goswami & Ghosh, 1997) and crystal engineering research (Goswami *et al.*, 1998). The design of highly specific solid-state compounds is of considerable significance in organic chemistry due to the important applications of these compounds in the development of new optical, magnetic and electronic systems (Lehn, 1992). The present work is part of a structural study of complexes of 2-aminopyridinium systems with hydrogen-bond donors and we report here the structure of 2-aminopyridinium–fumarate–fumaric acid (2/1/1), (I) (Fig. 1).

In (I), the 2-aminopyridinium ions are linked to the fumarate ions through  $\text{N1}—\text{H1}\cdots\text{O4}$  and  $\text{N2}—\text{H11}\cdots\text{O3}$  hydrogen bonds, resulting in the formation of cyclic eight-membered hydrogen-bonded rings (Fig. 1 and Table 2). The 2-aminopyridinium–fumarate–fumaric acid units are arranged so that

$\text{N1}—\text{H1}\cdots\text{O4}$ ,  $\text{N2}—\text{H11}\cdots\text{O3}$  and  $\text{O1}—\text{H10}\cdots\text{O4}$  hydrogen bonds form a two-dimensional network, with the networks connected *via*  $\text{N2}—\text{H12}\cdots\text{O3}$  hydrogen bonds, resulting in a three-dimensional network with a dihedral angle of  $79.0$  ( $2^\circ$ ) between the 2-aminopyridinium ions (Fig. 2).

The 2-aminopyridine–carboxylic acid system has been the subject of theoretical (Inuzuka & Fujimoto, 1990) and spectroscopic (Inuzuka & Fujimoto, 1986) amine–imine tautomerization studies. 2-Aminopyridine, like other organic bases, is protonated in acidic solution. The bonding of the H atom to the ring N atom of 2-aminopyridine rather than the amine N atom gives an ion for which an additional resonance structure can be written. As this monocation has more resonance energy (additional ionic resonance) than 2-aminopyridine itself, 2-aminopyridine is a strong base, like amidines (Acheson, 1967).

The present investigation, like our previous work (Büyükgüngör & Odabaşoğlu, 2002, 2003; Odabaşoğlu *et al.*, 2003), clearly shows that the positive charge in the 2-aminopyridinium ions of (I) is on the amine group. Our investigations also show that the 2-aminopyridinium cation is present in the crystal lattice as the *A* tautomeric form (see scheme below).

The  $\text{C1}—\text{N2}$  bond is approximately equal to a  $\text{C}=\text{N}$  double-bond length (Shanmuga Sundara Raj, Fun, Lu *et al.*, 2000), indicating that atom N2 of the amine group must also be  $sp^2$  hybridized. This is also supported by the  $\text{C1}—\text{N2}—\text{H11}$  angle of  $121.00$  ( $13^\circ$ ) and by the fact that atoms C1, N2, H11 and H12 lie in the pyridine plane, with a maximum deviation of  $0.018$  ( $7$ ) Å for atom N2 (Table 1). Similar bond distances and angles have been observed in 2-aminopyridinium succinate–succinic acid (Büyükgüngör & Odabaşoğlu, 2002) and 2-aminopyridinium adipate mono adipic acid dihydrate (Odabaşoğlu *et al.*, 2003), bis(2-aminopyridinium) maleate (Büyükgüngör & Odabaşoğlu, 2003) and in some 2-aminopyridine-containing molecules (Yang *et al.*, 1995; Grobelyn *et al.*, 1995; Shanmuga Sundara Raj, Fun, Zhao *et al.*, 2000).

The  $\text{C}=\text{C}$  bond length [ $1.311$  ( $3$ ) Å] of the fumaric acid molecule is somewhat shorter than the  $\text{C}=\text{C}$  bond length [ $1.319$  ( $3$ ) Å] of the fumarate ion. A similar bond length [ $1.323$  ( $3$ ) Å] was found in the maleate anion of bis(2-aminopyridinium) maleate (Büyükgüngör & Odabaşoğlu, 2003). The average  $\text{C}—\text{O}$  distances in the carboxylate groups that form intermolecular hydrogen bonds are  $1.32$  ( $2$ ) Å for the

hydroxyl C—OH bond and 1.21 (3) Å for the carbonyl C=O bond (Borthwick, 1980); the value for the carboxylate anion has been reported as 1.25 Å (Borthwick, 1980) (Table 1).

A packing diagram of (I), viewed along the *b* axis.

## Experimental

The title compound was prepared by mixing 2-aminopyridine and fumaric acid in a 1:1 molar ratio in water at 353 K. Crystals of (I) were obtained by slow evaporation of the solvent (m.p. 456–458 K).
