In the title complex of zinc(II) with 3,4,7,8-tetramethyl-1,10-phenanthroline (tmph), *viz.*  $[\text{Zn}(\text{C}_{16}\text{H}_{16}\text{N}_2)(\text{H}_2\text{O})_4](\text{S}_2\text{O}_3)$ , the metal atom has a monomeric octahedral  $\text{ZnN}_2\text{O}_4$  complex environment comprising two N-atom donors from the tmph group and four aqua O-atom donors. The complex cation is connected to four thiosulfate anions through a compact hydrogen-bonding network involving all coordinated aqua H-atom donors and all the outer acceptors (O and S) of the anion.

### Comment

The thiosulfate anion,  $\text{S}_2\text{O}_3^{2-}$ , is a highly versatile ligand, and metal complexes in which it does not bind to the cation are not common. A search of the April 2004 version of the Cambridge Structural Database (CSD; Allen, 2002) shows that the group acts as a counter-ion in fewer than 20% of the reported structures containing thiosulfate; in the remaining cases, it coordinates in a variety of different binding modes [for a brief review on the subject, see Freire, Baggio, Suescun & Baggio (2000), and references therein]. This behavior contrasts with those of some closely related oxyanions, *e.g.* sulfate, where the ratio rises to *ca* 50%.

When the anion does not coordinate, it tends to be involved in non-bonding interactions that are unusual either by virtue of their nature, as in  $[\text{Ni}(\text{bpy})_3](\text{S}_2\text{O}_3) \cdot 7\text{H}_2\text{O}$  (bpy is 2,2'-bipyridine; Freire, Baggio, Mombrú & Baggio, 2000), where two neighboring thiosulfates approach linearly head-to-head *via* a strikingly short S...S contact of 3.25 Å, or because of their quantity, as in the organic clathrate  $\text{C}_{36}\text{H}_{60}\text{N}_8^{6+} \cdot \text{S}_2\text{O}_3^{2-} \cdot 4\text{ClO}_4^- \cdot 11\text{H}_2\text{O}$  (Maubert *et al.*, 2001), in which the anion is involved in 12 strong hydrogen-bonding interactions.

We present here the structure of the monomeric zinc(II) complex with thiosulfate and 3,4,7,8-tetramethyl-1,10-phenanthroline (tmph), *viz.*  $[\text{Zn}(\text{tmph})(\text{H}_2\text{O})_4](\text{S}_2\text{O}_3)$ , (I), one of

the infrequent cases in which the anion does not bind to the cationic unit directly but is multiply connected through a dense network of hydrogen bonds.

The structure is shown in Fig. 1. The  $\text{N}_2\text{O}_4$  environment about the Zn atom is achieved through two N-atom donors of the tmph ligand [which imposes the only distortion to the coordination polyhedron through its small bite angle,  $77.6(2)^\circ$ ] and four water donor molecules. The result is a slightly distorted octahedral coordination with a narrow range of metal–N,O bond lengths [2.084 (5)–2.138 (6) Å; Table 1].

Analogous monomeric complexes with unsubstituted 1,10-phenanthroline instead of tmph molecules have been reported previously in the form of  $[\text{Zn}(\text{phen})(\text{H}_2\text{O})_4]^{2-}$ , the counter-ion(s) being either  $\text{SO}_4^{2-}$  (Zhang *et al.*, 1999) or  $2\text{NO}_3^-$  (Zhang & Janiak, 2001). No major differences are observed between these complexes and the present structure; a least-squares fit yielded mean deviations of 0.15 (1) and 0.12 (1) Å, respectively, for the 19 atoms that they have in common.

The tmph group is essentially planar [the mean deviation from the plane is 0.02 (1) Å] and binds to the cation with a small, though detectable, tilt [the angle between the N1/Zn/N2 and tmph planes is  $6.4(1)^\circ$ ].

**Figure 1**

As expected, the thiosulfate anion has an undistorted structure, with three S—O bond lengths that are indis-

**Figure 2**

A schematic view of the two-dimensional structures interacting with one another through the overlap of interleaved dmpH groups (in order to clarify the figure, two of these groups have been highlighted).

tinguishable within experimental error. A slight departure from the ideal arrangement is observed for the S—S—O angles, presumably arising from asymmetries in non-bonding contacts.

The packing of the structure is governed by the hydrogen-bonding interactions involving, as donors, all eight water H atoms and, as acceptors, the outer atoms of the thiosulfate anion (one S and three O), all of them fulfilling the role of double acceptors. This ‘one-to-one’ correspondence results in an approximately square geometry (in projection) of the hydrogen-bonding network around the thiosulfate anion (Fig. 2), and leads in turn to a two-dimensional structure perpendicular to the *c* axis in which each complex interacts with four counter-ions and *vice versa* (Table 2). The two-dimensional frameworks thus defined are concentrated in narrow regions at  $z \approx 0.25$  and  $z \approx 0.75$ , with the bulky dmpH groups protruding outwards from opposite ‘faces’ of the two-dimensional arrays, those on one side being at  $90^\circ$  to those on the other (Fig. 3). Neighboring planes are related by inversion centers promoting the interleaving of parallel aromatic groups at graphitic distances from each other. These  $\pi$ - $\pi$  interacting groups are separated by  $3.48(1) \text{ \AA}$ , with overlapping rings slipped by  $18.3(1)^\circ$  [where the slippage angle is that subtended by the ring normal and the center-to-center line (Janiak, 2000)].

### Experimental

The title compound was obtained by allowing a 96% ethanol solution of 3,4,7,8-tetramethyl-1,10-phenanthroline to diffuse into an equimolar aqueous solution containing zinc acetate and sodium thiosulfate (5 ml of each solution, all concentrations being 0.025 M). After *ca* six weeks of slow evaporation, a few (colorless) prismatic crystals suitable for X-ray analysis were obtained.

Symmetry codes: (i)  $\frac{3}{2} - x, y + \frac{1}{2}, \frac{1}{2} - z$ ; (ii)  $\frac{1}{2} - x, y + \frac{1}{2}, \frac{1}{2} - z$ ; (iii)  $x, y + 1, z$ .

H atoms on C atoms which were unambiguously defined by the stereochemistry were placed at calculated positions (C—H = 0.93 Å) and allowed to ride. In addition, terminal dmph methyl groups (C—H = 0.96 Å) were allowed to rotate, although their low rotational energy barrier may make the positions less well defined. Water H atoms were located from difference Fourier syntheses and refined with restrained O—H and H...H distances of 0.82 (1) and 1.36 (2) Å, respectively. All  $U_{\text{iso}}(\text{H})$  values were fixed at  $1.2U_{\text{eq}}$  of the parent atoms.

Data collection: *SMART-NT* (Bruker, 2001); cell refinement: *SAINT-NT* (Bruker, 2000); data reduction: *SAINT-NT*; program(s) used to solve structure: *SHELXS97* (Sheldrick, 1997); program(s) used to refine structure: *SHELXL97* (Sheldrick, 1997); molecular graphics: *XP* in *SHELXTL/PC* (Sheldrick, 1994); software used to prepare material for publication: *SHELXL97*.

The authors acknowledge the Spanish Research Council (CSIC) for providing a free-of-charge license to the CSD system and CIMAT for the purchase of the CCD detector.

Supplementary data for this paper are available from the IUCr electronic archives (Reference: JZ1648). Services for accessing these data are described at the back of the journal.
