The crystal structure of $\text{Ce}(\text{IO}_3)_3$ consists of one-dimensional chains of edge-sharing CeO_9 polyhedra which are crosslinked into two-dimensional layers through bridging IO_3^- groups. The layers are held together *via* long $\text{I}\cdots\text{O}$ contacts, resulting in an extended three-dimensional network. The $\text{I}-\text{O}$ bond distances and $\text{O}-\text{I}-\text{O}$ angles are normal, lying in the ranges $1.806(4)$ – $1.846(4)$ Å and $89.9(2)$ – $100.9(2)^\circ$, respectively. The three crystallographically independent iodate groups all show different coordination modes.

Comment

Metal iodates are of considerable interest because some of these compounds exhibit piezoelectric and pyroelectric effects, and they have potential applications in second-harmonic generation (Morosin *et al.*, 1973). $\text{Ce}(\text{IO}_3)_3$ was previously synthesized by Abrahams *et al.* (1976), who predicted it to be isostructural with $\text{Gd}(\text{IO}_3)_3$ (Liminga *et al.*, 1977), in space group $P2_1/a$, with $a = 13.56(2)$ Å, $b = 8.565(9)$ Å, $c = 7.214(12)$ Å, $\beta = 99.7(3)^\circ$ and $V = 826(2)$ Å³. Recently, Douglas *et al.* (2004) re-investigated the rare earth iodates and reported the lattice constants of all anhydrous $4f$ -iodates, except for those of $\text{Ce}(\text{IO}_3)_3$. They found that $\text{Ln}(\text{IO}_3)_3$ compounds (Ln is Pr, Nd, Sm, Eu, Gd, Tb, Ho or Er) crystallize in a $\text{Gd}(\text{IO}_3)_3$ -type structure. In the course of our research on novel iodate non-linear optical (NLO) materials, we have obtained single crystals of $\text{Ce}(\text{IO}_3)_3$. Our X-ray structural analysis indicated that the newly prepared $\text{Ce}(\text{IO}_3)_3$ is a new polymorph, with cell dimensions different from those given by Abrahams *et al.* We report the crystal structure here.

In the structure of $\text{Ce}(\text{IO}_3)_3$, each Ce^{3+} ion is coordinated to nine O atoms in a distorted monocapped square-antiprismatic geometry, as shown in Fig. 1. The $\text{Ce}-\text{O}$ distances of $2.420(4)$ – $2.809(5)$ Å (average 2.556 Å; Table 1) are very reasonable when compared with the ranges $2.427(3)$ – $2.803(3)$ Å (average 2.536 Å) in $\text{Ce}_2(\text{SO}_4)_3 \cdot 5\text{H}_2\text{O}$ (Junk *et al.*, 1999) and $2.496(3)$ – $2.519(3)$ Å (average 2.511 Å) in $\text{Ce}(\text{HSO}_4)_3$ (Wickleder, 1998), all featuring nine-coordinate Ce.

The CeO_9 polyhedra share edges with each other to form zigzag chains parallel to the b axis (Fig. 2). There are two sets of $\text{Ce}\cdots\text{Ce}$ distances within the chains, *viz.* $4.2878(7)$ and $4.5070(7)$ Å. The longer $\text{Ce}^i\cdots\text{Ce}^{ii}$ contacts are associated with pairs of Ce atoms double-bridged through I_3O_7^- groups (sharing the $\text{O}_9\cdots\text{O}_9^{iii}$ edge), while the shorter ones ($\text{Ce}\cdots\text{Ce}^i$) are those involved in the two bridging I_2O_5^- and two bridging I_3O_7^- groups (sharing the $\text{O}_6\cdots\text{O}_6^i$ edge) [symmetry codes: (i) $1-x, 1-y, 1-z$; (ii) $x, 1+y, z$; (iii) $1-x, 2-y, 1-z$]. These chains are crosslinked by IIO_3^- groups *via* μ_2 -bridging O atoms, resulting in a two-dimensional layer parallel to the (101) plane. Adjacent layers are further connected together through long $\text{I}\cdots\text{O}$ contacts [$\text{I}_2\cdots\text{O}_2 = 2.779(5)$ Å, $\text{I}_2\cdots\text{O}_5 = 2.390(5)$ Å, $\text{I}_3\cdots\text{O}_2 = 2.738(5)$ Å and $\text{I}_3\cdots\text{O}_7 = 2.851(5)$ Å], giving rise to an extended three-dimensional network.

Figure 1

The coordination geometry about the Ce atom. The double-shaded circle denotes a Ce atom and open circles denote O atoms. The monocapped square antiprism is indicated by thin lines. See Table 1 for symmetry codes.

Figure 2

The $\text{Ce}(\text{IO}_3)_3$ layer parallel to the (101) plane, with displacement ellipsoids drawn at the 50% probability level. [Symmetry codes: (i) $1-x, 1-y, 1-z$; (ii) $x, 1+y, z$; (iii) $1-x, 2-y, 1-z$.]

There are three crystallographically unique iodate groups, which adopt different coordination modes toward Ce³⁺ ions (Fig. 2). Each IO₃⁻ group is a bidentate ligand bonded to two Ce³⁺ centres via two μ₂-O atoms, each IO₃⁻ group functions as a tridentate ligand, chelating one Ce³⁺ and coordinated to a second Ce³⁺ ion through a μ₃-O atom, while each of the IO₃⁻ groups acts as a tetradentate ligand that chelates one Ce³⁺ centre and simultaneously binds the other two via a μ₂-O and a μ₃-O atom, respectively. Despite the difference in the coordination schemes of the iodate groups, the I—O bond lengths of 1.806 (4)–1.846 (4) Å and the O—I—O angles of 89.9 (2)–100.9 (2)° show no particular distortions and are within the ranges observed previously for inorganic iodates (Douglas *et al.*, 2004). Bond-valence-sum (Brown & Altermatt, 1985) calculations give values of 3.14 for Ce and 4.74–4.93 for I atoms, in reasonable agreement with their expected formal valences.

The crystal structure of Ce(IO₃)₃ presented here is different from that previously reported by Abrahams *et al.* (1976). The latter contains a three-dimensional network consisting of irregular CeO₈ polyhedra bridged by bi- and tridentate IO₃⁻ ligands. It is the difference in the coordination modes of the iodate groups, as well as the variation in the Ce³⁺ coordination geometry, that is responsible for the structural versatility of Ce(IO₃)₃.

Experimental

The title compound was synthesized using hydrothermal techniques. All reagents were of analytical grade. Ce(NO₃)₃·6H₂O (0.106 g, 0.244 mmol), I₂O₅ (0.287 g, 0.860 mmol) and H₂O (5 ml) were sealed in a 25 ml Teflon-lined autoclave. This was heated in an oven at 443 K for one week under autogenously generated pressure, then cooled slowly to room temperature. The product consisted of yellow block-shaped crystals, with largest dimensions of 0.6 × 0.8 × 1.0 mm, covered by a colourless liquid. The final pH of the reaction system was about 1.0. The crystals were isolated in about 84% yield (based on Ce) by washing the reaction product with deionized water and anhydrous ethanol, followed by drying with anhydrous acetone. Powder X-ray diffraction analysis revealed that the product is a single phase of Ce(IO₃)₃ and no lines due to impurity phases were observed. In previous work (Douglas *et al.*, 2004), Ln(IO₃)₃ compounds (Ln is Pr, Nd, Sm, Eu, Gd, Tb, Ho or Er) were prepared by decomposition of the corresponding periodates under hydrothermal conditions. Here, the Ce analogue was synthesized directly from the hydrothermal reaction of Ce(NO₃)₃ with I₂O₅. I₂O₅ was found to play an important role in the crystal growth of Ce(IO₃)₃. The replacement of I₂O₅ by H₅IO₆ as an iodine source did not generate any crystalline products, instead forming lumps of amorphous gel.

Crystal data

Ce(IO ₃) ₃	$D_x = 5.431 \text{ Mg m}^{-3}$
$M_r = 664.82$	Mo $K\alpha$ radiation
Monoclinic, $P2_1/n$	Cell parameters from 25 reflections
$a = 8.9188 (10) \text{ \AA}$	$\theta = 16.8\text{--}22.5^\circ$
$b = 5.9619 (11) \text{ \AA}$	$\mu = 17.01 \text{ mm}^{-1}$
$c = 15.4047 (12) \text{ \AA}$	$T = 290 \text{ K}$
$\beta = 96.974 (8)^\circ$	Plate, yellow
$V = 813.05 (19) \text{ \AA}^3$	$0.10 \times 0.08 \times 0.05 \text{ mm}$
$Z = 4$	

Table 1
Selected geometric parameters (Å).

Ce—O6 ⁱ	2.420 (4)	Ce—O7 ⁱⁱⁱ	2.529 (5)
Ce—O3 ⁱⁱ	2.480 (4)	Ce—O4	2.567 (4)
Ce—O8	2.485 (4)	Ce—O6	2.700 (5)
Ce—O9 ⁱ	2.506 (4)	Ce—O9 ⁱⁱⁱ	2.809 (5)
Ce—O1	2.507 (4)		

Symmetry codes: (i) $1 - x, 1 - y, 1 - z$; (ii) $\frac{1}{2} - x, y - \frac{1}{2}, \frac{1}{2} - z$; (iii) $x, y - 1, z$.

Data collection

Rigaku AFC-7R diffractometer	$R_{\text{int}} = 0.043$
$2\theta/\omega$ scans	$\theta_{\text{max}} = 35.0^\circ$
Absorption correction: ψ scan (Kopfmann & Huber, 1968)	$h = 0 \rightarrow 14$
$T_{\text{min}} = 0.201, T_{\text{max}} = 0.420$	$k = 0 \rightarrow 9$
4133 measured reflections	$l = -24 \rightarrow 24$
3582 independent reflections	3 standard reflections
3317 reflections with $I > 2\sigma(I)$	every 150 reflections
	intensity variation: $\pm 1.7\%$

Refinement

Refinement on F^2	$(\Delta/\sigma)_{\text{max}} < 0.001$
$R[F^2 > 2\sigma(F^2)] = 0.032$	$\Delta\rho_{\text{max}} = 2.86 \text{ e \AA}^{-3}$
$wR(F^2) = 0.087$	$\Delta\rho_{\text{min}} = -2.67 \text{ e \AA}^{-3}$
$S = 1.17$	Extinction correction: <i>SHELXL97</i>
3582 reflections	(Sheldrick, 1997)
119 parameters	Extinction coefficient: 0.0060 (2)
$w = 1/[\sigma^2(F_o^2) + (0.0357P)^2 + 9.4569P]$	
where $P = (F_o^2 + 2F_c^2)/3$	

Direct phase determination yielded the positions of the Ce and I atoms. The remaining O atoms were located in subsequent difference Fourier syntheses. All atoms were refined anisotropically. The highest residual electron-density peaks were located 0.69 Å from the Ce atoms.

Data collection: *Rigaku/AFC Diffractometer Control Software* (Rigaku, 1994); cell refinement: *Rigaku/AFC Diffractometer Control Software*; data reduction: *Rigaku/AFC Diffractometer Control Software*; program(s) used to solve structure: *SHELXS97* (Sheldrick, 1997); program(s) used to refine structure: *SHELXL97* (Sheldrick, 1997); molecular graphics: *SCHAKAL92* (Keller, 1992); software used to prepare material for publication: *SHELXL97*.

Supplementary data for this paper are available from the IUCr electronic archives (Reference: FA1123). Services for accessing these data are described at the back of the journal.
